numerous small bruises on both arms and both legs, besides other bruises, small and large, on the body and buttocks.'

As we have said, it would be wrong for us at this stage to comment upon the case from any medico-legal point of view. The prisoner, who is under remand, has been stated in the press to be a medical man, but we have been unable to find his name in the Medical Register.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Brighton Urban Sanitary District.—Dr. Arthur Newsholme has arranged for his annual report for 1894 several interesting diagrams in which the excess or defect in the death-rate, &c., above the mean for the last twenty-five years is well set forth. During 1894 the illegitimate births proved to be a proportion in excess of any since the year 1883. Commenting upon the effect of a diminishing birth-rate upon the death-rate, Dr. Newsholme points out that, although for a time a diminished birth-rate tends rather to lower the death-rate, its continuance for another forty or fifty years would have the effect of increasing the proportion of persons at ages above fifty-five or so, and so of raising the general death-rate. This general effect is, he points out, anticipated in the case of Brighton by the fact that a large number of aged persons settle there. For instance, in the 1891 census it was shown that for every 1000 persons living at all ages in the respective towns there were at ages above fifty-five, 121 in Brighton, 101 in Croydon, 93 in Huddersfield, and 85 in Derby. Under five years of age, however, the figures were for Huddersfield 98, Brighton 103, Croydon 114, and Derby 119. During 1894 the recorded death-rate for Brighton was 16·4, the corrected 16·6, the death-rate of the most densely populated ward being 18·6 per 1000, as against 13·3 for the rest of the borough. In dealing with the death-rate from phthisis—which is, by the way, showing a tendency downwards—Dr. Newsholme remarks that in several cases death occurred within a few weeks of the patient's arrival in Brighton. He strongly deprecates the sending of patients to the seaside in the last stage of phthisis. In two cases of small-pox the evidence obtained pointed to some "Sunlight Soap" coupons from an infected district as having been the means of conveying the disease. Fifty-three cases of enteric fever had their origin in Brighton during 1894, and after making a careful and exhaustive inquiry into the history of the cases Dr. Newsholme came to the conclusion that no less than fifteen of them were caused by sewage-contaminated oysters, while six others, he states, were ascribable to other contaminated shell-fish eaten in an uncooked condition. He further remarks that of the remaining thirty-two cases, in seven no definite history was obtainable and in twenty-five shell-fish as a cause was excluded. From this summary Dr. Newsholme observes: "It will be seen that at least 40 per cent. of the cases of enteric fever originating in Brighton during last year were ascribable to sewage-contaminated shell-fish, a fact of the practical bearings of which it is my duty to warn the public of Brighton."

Finchley Urban Sanitary District.—Dr. H. R. Kenwood records in his current annual report for this district an interesting outbreak of throat affection which resembled diphtheria, but which apparently could not be regarded as that disease. It seems to have been an infectious follicular tonsillitis. Dr. Kenwood considers that the evidence pointed strongly to milk as having been the agent by which the disease was conveyed. On examining the cows which furnished milk to the infected area Dr. Kenwood discovered that three of them were evidently out of health; in each case the teats were slightly ulcerated, and one of the cows had a small chronic abscess in the udder. Dr. Kenwood was further able to demonstrate the very important fact that though the milk from these cows was distributed to only 17 per cent. of the total houses in the district it supplied no less than 94 per cent. of the houses infected. This certainly appears to be very strong evidence. Commenting upon the above outbreak Dr. Kenwood observes that the machinery for preventing occurrences of this kind is not all that it should be. He considers that a regular and systematic inspection of the cows in each district should be made at short intervals, and that a veterinary expert should be appointed by several sanitary authorities in combination. It is, Dr. Kenwood says, somewhat strange that although these milk-borne epidemics are frequently cropping up, there is nothing done to prevent their recurrence, and that all action is aimed at preventing the spread of an outbreak after much damage has been already affected. With Dr. Kenwood's views we have much sympathy, and we have frequently suggested in our columns similar action. A short time since, in reference to the report of the Royal Commission on Tuberculosis, we expressed a hope that it would lead to some regular inspection of milch cows and their surroundings.

Southport Urban Sanitary District.—The age and sex grouping of the population of Southport (44,928) is, Dr. Henry Vernon observes, a peculiar one, as compared with a normal English grouping in a population of the same number. Under fifteen years of age the population of Southport shows a deficit of 2643 persons, while in practically all the age groupings over fifteen Southport has an excess of persons as compared with the population of England and Wales as a whole. In every 1000 of the Southport population there are 590·710 females and 409·290 males, as compared with 515·286 females and 484·714 males in England and Wales, as evidenced by the 1891 census. Dr. Vernon estimates the local death-rate for 1894 as 14·32 per 1000, the corrections made consisting of the addition to the deaths occurring in the borough of those dying outside but belonging to the district, together with a subtraction of moribund visitors and an allowance for the gain derived from the peculiar age and sex distribution of the population. In commenting upon the calculation of a local death-rate Dr. Vernon observes: "If it tends to evolve a true biometric result to 'count in' the deaths of persons who may have left Southport ten or twenty years ago to seek the shelter of Ormskirk workhouse it cannot tend to an untrue result to 'count out' the deaths of those who have only been with us a few weeks, and who were known to have arrived stricken with mortal sickness. The inevitable conclusion seems to be that a time limit should be fixed after which deaths should be debited to the localities where they actually occur."

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN thirty-three of the largest English towns 5616 births and 4225 deaths were registered during the week ending Aug. 10th. The annual rate of mortality in these towns, which had been 22·5 and 20·7 per 1000 in the two preceding weeks, was last week 20·8. In London the rate was equal to 19·0 per 1000, while it averaged 22·1 in the thirty-two provincial towns. The lowest rates in these towns were 13·6 in Croydon, 14·2 in Huddersfield, 14·6 in Bristol, 15·3 in Brighton, and 15·5 in Portsmouth; the highest rates were 26·8 in Salford, 27·1 in Manchester, 30·5 in Liverpool, 31·0 in Wolverhampton, and 33·8 in Preston. The 4225 deaths included 1077 which were referred to the principal zymotic diseases, against 1206 and 1178 in the two preceding weeks; of these, 736 resulted from diarrhœa, 109 from measles, 76 from diphtheria, 65 from whooping-cough, 46 from "fever" (principally enteric), 39 from scarlet fever, and 6 from small-pox. The lowest death-rates from these diseases were recorded in Plymouth, Bristol, Huddersfield, Halifax, and Newcastle-upon-Tyne; and the highest rates in Liverpool, Bolton, Preston, Wolverhampton, and Norwich. The greatest mortality from measles occurred in West Ham, Manchester, and Blackburn; from whooping-cough in Oldham; and from diarrhœa in Liverpool, Hull, Sheffield, Leicester, Bolton, Preston, Wolverhampton, and Norwich. The mortality from scarlet fever and from "fever" showed no marked excess in any of the large towns. The 76 deaths from diphtheria included 55 in London, 4 in West Ham, and 3 in Liverpool. Three fatal cases of small-pox were registered in London, 2 in Oldham, and 1 in Liverpool, but not one in any other of the thirty-three towns. There were 273 cases of small-pox under treatment in the Metropolitan Asylum Hospitals and in the Highgate Small-pox Hospital on Saturday last, Aug. 10th., against 89, 199, and 237 at the end of the three preceding weeks; 54 new cases were admitted during the week, against 23, 115, and 60 in the three preceding weeks. The number of scarlet

Digitized by Google

fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 2511, against 2267, 2347, and 2423 on the three preceding Saturdays; 281 new cases were admitted during the week, against 220, 249, and 247 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 185 and 171 in the two preceding weeks, further declined to 159 last week, and were 23 below the corrected average. The causes of 46, or 1·1 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Cardiff, Oldham, Bradford, Sunderland, and in eleven other smaller towns; the largest proportions of uncertified deaths were registered in Birkenhead, Liverpool, and Sheffield.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 18·3 and 18·0 per 1000 in the two preceding weeks, further declined to 17·6 during the week ending Aug. 10th, and was 3·2 per 1000 below the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 16·0 in Edinburgh and 17·1 in Leith to 19·6 in Paisley and 20·9 in Greenock. The 509 deaths in these towns included 68 which were referred to diarrhœa, 17 to whooping-cough, 8 to measles, 4 to scarlet fever, 4 to "fever," 1 to diphtheria, and not one to small-pox. In all, 102 deaths resulted from these principal zymotic diseases, against 92 and 84 in the two preceding weeks. These 102 deaths were equal to an annual rate of 3·5 per 1000, which was 1·8 below the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of diarrhœa, which had been 64 and 55 in the two preceding weeks, rose again to 68 last week, of which 34 occurred in Glasgow, 8 in Edinburgh, 8 in Dundee, and 6 in Greenock. The deaths referred to whooping-cough, which had been 7 and 12 in the two preceding weeks, further rose to 17 last week, and included 5 in Glasgow and 5 in Dundee. The 8 fatal cases of measles exceeded by one the number in the preceding week, and included 5 in Glasgow. The deaths from scarlet-fever, which had been 3 in each of the two preceding weeks, were 4 last week, of which 3 occurred in Glasgow, where 2 of the 4 fatal cases of "fever" were also recorded. The deaths referred to diseases of the respiratory organs in these towns, which had been 59 and 77 in the two preceding weeks, declined to 67 last week, but were 11 above the number in the corresponding week of last year. The causes of 23, or nearly 5 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 23·9 and 25·7 per 1000 in the two preceding weeks, declined again to 22·2 during the week ending Aug. 10th. During the past six weeks of the current quarter the death-rate in the city has averaged 23·6 per 1000, the rate during the same period being 20·0 in London and 15·9 in Edinburgh. The 149 deaths registered in Dublin during the week under notice showed a decline of 23 from the number in the preceding week, and included 27 which were referred to the principal zymotic diseases, against 28 and 25 in the two preceding weeks; of these, 23 resulted from diarrhœa, 3 from "fever," 1 from whooping-cough, and not one either from small-pox, measles, scarlet fever, or diphtheria. These 149 deaths were equal to an annual rate of 4·0 per 1000, the zymotic death-rate during the same period being 4·7 in London and 2·3 in Edinburgh. The fatal cases of diarrhœa, which had been 16, 24, and 17 in the three preceding weeks, rose again to 23 last week. The 3 deaths referred to different forms of "fever" exceeded those recorded in any recent week, while the mortality from whooping-cough showed a further decline. The 149 deaths in Dublin last week included 46 of infants under one year of age, and 19 of persons aged upwards of sixty years; the deaths of infants showed an increase upon the number in the preceding week, while those of elderly persons were considerably below the number recorded in any recent week. Three inquest cases and 3 deaths from violence were registered; and 29, or nearly one-fifth, of the deaths occurred in public institutions. The causes of 17, or more than 11 per cent., of the deaths in the city last week were no certified.

VITAL STATISTICS OF LONDON DURING JULY, 1895.

In the accompanying table will be found summarised complete statistics relating to sickness and mortality during July in each of the forty-three sanitary areas of London. With regard to the notified cases of infectious disease in the metropolis during last month, it appears that the number of persons reported to be suffering from one or other of the nine diseases specified in the table was equal to 11·6 per 1000 of the population, estimated at 4,392,346 persons in the middle of the current year. In the three preceding months the rates had been 5·7, 6·8, and 8·4 per 1000 respectively. Among the various sanitary areas the rates were considerably below the average in Westminster, St. James Westminster, Stoke Newington, St. Olave Southwark, Bermondsey, Wandsworth, and Lee; while they showed the largest excess in Chelsea, Bethnal Green, Whitechapel, St. George-in-the-East, Limehouse, Mile End Old Town, and Greenwich. The prevalence of small-pox in London showed a marked increase in July, 258 cases being notified during the month, including 59 in Whitechapel, 31 in St. George Southwark, 24 in Mile End Old Town, 18 in Bethnal Green, and 15 in Camberwell sanitary areas. The Metropolitan Asylum Hospitals contained 232 small-pox patients at the end of July, against 34, 20, and 33 at the end of the three preceding months; the weekly admissions averaged 49, against 7, 5, and 10 in the three preceding months. The prevalence of scarlet fever in London showed a further marked increase upon that recorded in recent months; this disease was proportionally most prevalent in Chelsea, St. George Hanover-square, Strand, Shoreditch, Whitechapel, St. George-in-the-East, Limehouse, and Mile End Old Town sanitary areas. The Metropolitan Asylum Hospitals contained 2340 scarlet fever patients at the end of July, against 1413, 1481, and 1845 at the end of the three preceding months; the weekly admissions averaged 263, against 132, 167, and 229 in the three preceding months. The prevalence of diphtheria in London showed a further increase during July; among the various sanitary areas this disease showed the highest proportional prevalence in Chelsea, Bethnal Green, Whitechapel, St. George-in-the-East, Mile End Old Town, Poplar, and Rotherhithe. There were 680 cases of diphtheria under treatment in the Metropolitan Asylum Hospitals at the end of July, against 430, 508, and 633 at the end of the three preceding months; the weekly admissions averaged 103, against 69, 81, and 109 in the three preceding months. The prevalence of enteric fever in London showed a slight increase during July; this disease was proportionally most prevalent in Hackney, St. Luke, Shoreditch, Limehouse, Woolwich, and Plumstead sanitary areas. Erysipelas was proportionally most prevalent in Marylebone, Shoreditch, Bethnal Green, Limehouse, and Mile End Old Town sanitary areas. The 18 cases of puerperal fever notified during July included 3 in Islington, and 2 each in Fulham, Lambeth, Wandsworth, and Lewisham sanitary areas.

The mortality statistics in the accompanying table relate to the deaths of persons actually belonging to the various sanitary areas, the deaths occurring in the institutions of London having been distributed among the different sanitary areas in which the patients had previously resided. During the five weeks ending Saturday, Aug. 3rd, the deaths of 8851 persons belonging to London were registered, equal to an annual rate of 21·0 per 1000 of the population, against 18·3, 15·9, and 14·9 in the three preceding months. The lowest death-rates during July in the various sanitary areas were 8·9 in Hampstead, 10·5 in Lee, 11·3 in St. James Westminster, 11·5 in Stoke Newington, 12·4 in Plumstead, and 12·7 in St. George Hanover-square; the highest rates were 29·2 in Whitechapel, 29·4 in St. Saviour Southwark, 29·5 in St. Olave Southwark, 29·8 in Holborn, 31·0 in Mile End Old Town, 35·2 in Limehouse, 39·0 in St. George-in-the-East, and 47·3 in St. Luke. During the five weeks of July 2463 deaths were referred to the principal zymotic diseases in London; of these, 1576 resulted from diarrhœa, 391 from measles, 242 from diphtheria, 111 from whooping-cough, 93 from scarlet fever, 44 from different forms of "fever" (including 42 from enteric fever and 2 from ill-defined forms of continued fever), and 6 from small-pox. These 2463 deaths were equal to an annual rate of 5·8 per 1000. The lowest zymotic death-rates were recorded in St. George Hanover-square, St. James Westminster, Hampstead, City of London, Lee, and Plumstead; and the highest rates in St. Luke, Shoreditch, Bethnal Green, St. George-in-the-East, Limehouse, Mile

* Including 41 cases of membranous croup.

† Including deaths from membranous croup.

Digitized by Google

End Old Town, and St. George Southwark sanitary areas. Six fatal cases of small-pox were registered in London during the month under notice, the corrected average in the corresponding periods of the ten preceding years being 10; of these 6 fatal cases 3 belonged to Camberwell, 2 to Strand, and 1 to St. Pancras sanitary areas. The 391 deaths referred to measles were 99 above the corrected average number; among the various sanitary areas this disease showed the highest proportional fatality in St. Luke, Whitechapel, St. George-in-the-East, Limehouse, Mile End Old Town, Poplar, and Bermondsey. The 93 fatal cases of scarlet fever were within 3 of the corrected average number; this disease showed the highest proportional fatality in the Strand, St. Saviour Southwark, and Woolwich sanitary areas. The 242 deaths referred to diphtheria exceeded by 91 the corrected average number; among the various sanitary areas this disease showed the highest proportional fatality in Fulham, St. Luke, Bethnal Green, Whitechapel. St. George-in-the-East, Limehouse, Mile End Old Town, Camberwell, and Greenwich. The 111 fatal cases of whooping-cough were less than half the corrected average number; this disease showed the highest proportional fatality in Fulham, Clerkenwell, St. George Southwark, Newington, and Lambeth sanitary areas. The 42 deaths referred to enteric fever were 9 below the corrected average number; there was no marked excess of "fever" mortality last month in any of the sanitary areas. The 1576 fatal cases of diarrhœa exceeded by as many as 517 the corrected average number; among the various sanitary areas this disease showed the highest proportional fatality in St. Luke, Shoreditch, Bethnal Green, St. George-in-the-East, Limehouse, Mile End Old Town, St. George Southwark, and Lambeth. In conclusion, it may be stated that the mortality in London during July from these principal zymotic diseases was more than 31 per cent. above the average, owing principally to the excessive fatality of summer diarrhœa.

Infant mortality in London during July, measured by the proportion of deaths under one year of age to registered births, was equal to 289 per 1000, and considerably exceeded the average. Among the various sanitary areas the lowest rates of infant mortality were recorded in St. George Hanover-square, Hampstead, Stoke Newington, Lee, Lewisham, Woolwich and Plumstead; and the highest rates in St. Giles, Clerkenwell, St. Luke, Shoreditch, St. George-in-the-East, St. Saviour Southwark, and St. George Southwark.

THE SERVICES.

ARMY MEDICAL STAFF.

Brigade-Surgeon-Lieutenant-Colonel John Henry Hughes, M.D., to be Surgeon-Colonel, vice S. Archer, retired. Surgeon-Lieutenant-Colonel Richard Exham to be Brigade-Surgeon-Lieutenant-Colonel, vice R. N. Mally, deceased. Surgeon-Lieutenant-Colonel James Macnamara, M.D., to be Brigade-Surgeon-Lieutenant-Colonel, vice J. H. Hughes, M.D. The undermentioned Surgeons on probation are gazetted as Surgeon-Lieutenants:—Lionel Fergus Smith, M.B.; Robert James Blackham; Septimus Harold Fairrie, M.B.; George Thelwall Kindersley Maurice; Rupert Fawssett; John Vincent Forrest, M.B.; Henry William Grattan; Francis Ernest Gunter; John Hay Campbell; and John Grech.

INDIA AND THE INDIAN MEDICAL SERVICES.

Brigade-Surgeon-Lieutenant-Colonel and Temporary Surgeon-Colonel William Roe Hooper is granted the temporary rank of Surgeon-Major-General. The services of Surgeon-Captain H. B. Melville, M.B., C.M., are replaced temporarily at the disposal of the Military Department. Surgeon-Major C. Monks has delivered over charge of the office of the Superintendent of Mahabaleshvar. Surgeon-Captain T. E. Dyson, M.B., C.M., and Surgeon-Major K. S. Nariman have respectively delivered over and received charge of the office of the Deputy Sanitary Commissioner, Gujarat Registration District. Surgeon-Captain G. B. Russell, A.M.S., is appointed Personal Assistant to the Principal Medical Officer, Madras Command. The services of the undermentioned medical officers of the Bengal Establishment are placed permanently at the disposal of the Government of the North-West Provinces and Oudh:—Surgeon-Captain C. C. Manifold; Surgeon-Major G. M. J. Giles, M.B., F.R.C.S.; and Surgeon-Captain J. M. Crawford, M.B., C.M.

NAVAL MEDICAL SERVICE.

The following appointments are announced:—Staff-Surgeon John D. Henwood to the *Devastation*; Surgeon S. Walter Bowden, D.S.O., to the *Urgent*.

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Lieutenant Herbert Woodley Joyce, 2nd Volunteer Battalion the Buffs (East Kent Regiment), to be Surgeon-Lieutenant.

VOLUNTEER CORPS.

Artillery: 2nd Glamorganshire: Surgeon-Lieutenant P. R. Griffiths, M.B., resigns his commission. *Royal Engineers:* 1st Sussex: Second-Lieutenant G. A. Skinner is appointed Surgeon-Lieutenant. *Rifle:* 1st Surrey (South London): Surgeon-Lieutenant W. A. Atkinson, M.B., to be Surgeon-Captain.

CHITRAL.

The future of Chitral appears to be pretty well settled. The policy adopted by the present Government is not to remove altogether the troops from that country, but to maintain a hold on it by retaining a native force at Chitral and by utilising the services of native levies and the aid of the Khan of Dir's troops for the protection of the country in the vicinity of that station. Surgeon-Major Sir George Robertson will shortly proceed to Chitral in connexion with a settlement of the country. A force composed of a battalion of Goorkhas and one of the Punjab Infantry, with guns, will garrison Chitral, but no British troops will remain across the frontier. This policy of compromise is stated to have been received with much satisfaction by the Government of India. The Chitral expedition has not only shown the gallantry of the troops taking part in it, especially of the native portion, but it has afforded the medical service of India an opportunity of exhibiting its bravery and devotion. In other respects also the expedition has been productive of some good. The Chitral war has shown the practical impossibility of invading India from the north-west by a large force from Central Asia. The topographical difficulties in the way of marching any large army over such mountainous tracts of country would probably prove for Russia an insurmountable task. The experience we have gained in this expedition of the Lee-Metford rifle in action has moreover led to an investigation which will probably add to our present knowledge in regard to arms of precision and the surgery of modern warfare.

THE COMPETITIVE EXAMINATIONS FOR HER MAJESTY'S MEDICAL SERVICES.

The following are the lists of successful candidates at the recent examinations:—

BRITISH MEDICAL SERVICE.

Name.	Marks.	Name.	Marks
F. S. Brereton	2685	M. L. M. Vaudin	2213
J. C. B. Stratham	2324	W. A. Ward	2167
P. J. Probyn	2265	E. G. Forrest	2053
R. M. le H. Cooper	2259	A. W. Hooper	2005
A. H. Waring	2214	E. C. Hayes	2001

INDIAN MEDICAL SERVICE.

Name.	Marks.	Name.	Marks.
W. W. Clemesha	2605	C. R. Bakhla	2279
A. W. R. Cochrane	2594	K. V. Kirkday	2260
V. E. H. Lindesay	2500	E. R. Rost	2254
R. P. Wilson	2446	C. B. Harrison	2238
N. R. J. Rainier	2441	W. J. Niblock	2227
E. L. Perry	2423	E. Le F. Payne	2223
J. A. Black	2411	N. P. O'G. Lalor	2222
J. H. Symons	2337	J. C. Robertson	2212

THE ARMY AND NAVY ESTIMATES.

The estimates having been framed by the preceding, and accepted by the present, Government, their discussion will not give much room for adverse criticism on the part of the Opposition. The question of who is to be the successor to the Duke of Cambridge must be settled, and the policy in regard to Chitral and other matters will probably be discussed. It seems to be generally assumed that Lord Wolseley will succeed the Duke of Cambridge in the newly created appointment, and his rank and reputation, his military services, and proved ability and experience point him out as the man best fitted for the post. We can only hope that his Lordship will be just and generous in his dealings with the Army Medical Services.

THE EX-MINISTER FOR INDIA.

The retirement of no one of the ex-Ministers of the late Government will probably be more regretted in India than that of Sir Henry Fowler from the post he filled at the India Office. Apart from all party considerations, Sir Henry Fowler's speeches and conduct in regard to the opium question and

Digitized by Google

other matters showed that he had a manly, independent, and judicial way of considering and discussing Indian questions and a firm "grip" of his subjects. In saying this we are only expressing what was, we believe, the general opinion on both sides of the House, which was endorsed in India.

DEATH IN THE SERVICES.

With regret we announce the death of Brigade-Surgeon John Proudfoot Stratton, Bombay Army (retired), Political Agent, Bundelkund, in his sixty-seventh year. He took part in the Indian Mutiny Campaign, and retired in 1886.

Under the provisions of an Order in Council Surgeon George Fletcher Collins, of H.M.S. *Pembroke*, Chatham, withdraws from the Royal Navy, with a gratuity of £1000, after eight years' service.

Correspondence.

"Audi alteram partem."

"NOTE ON A RARE CONDITION OF THE OMENTUM."

To the Editors of THE LANCET.

SIRS,—The condition described in your columns of Aug. 10th by Mr. Greig Smith is one which falls exactly into place in a small group of cases, somewhere about ten in number, in my own experience. They are all exactly alike, and the state and appearance of the vessels are exactly described by Mr. Greig Smith when he says that they "resembled fat, well-developed earthworms." The group of cases I refer to constitutes one of the many outlying corners of abdominal surgery which I have been struggling to get into book shape for some years, but so far unsuccessfully. The cases are certainly those in which a pelvic tumour has become rotated and slowly strangulated—acute strangulation has an altogether different history and result. The slow strangulation results in a union to the tumour of the fringe of the omentum, the gradual increase of the vessels of the apron, and the separation of the tumour from its original stock, with a final transplantation on to the omentum. The complete history of this process is built up in a series of my own observations, and is quite substantiated by isolated observations of other surgeons published here and there. The tumours in which this transplantation occurs are chiefly ovarian, but are also occasionally myomatous. Generally their pelvic pedicle has disappeared by the time matters have reached the stage noted in Mr. Greig Smith's case. He says nothing about a pelvic pedicle (though he says the tumour was pelvic), and therefore I assume it had disappeared. If the tumour was originally a strangulated uterine myoma he will find no evidence now of a pedicle on the tumour, but in a separated ovarian tumour it would not be difficult to do so.

I am, Sirs, yours obediently,

The Crescent, Birmingham, Aug. 12th, 1895. LAWSON TAIT.

A MODERN PANACEA.

To the Editors of THE LANCET.

SIRS,—Being at my wits' end for a means of curing a case of ringworm of the scalp which had flourished under treatments many and various, I in May last began to treat it with the solution of the biniodide of mercury. The hair was removed, the crusts were washed carefully away, and the biniodide solution was applied thoroughly by myself, three times a week at first, then every day. At the end of a month the result was *nil*, or almost *nil;* any little improvement that there was might be accounted for by the extra cleanliness and care taken in keeping the hair short and the scalp free from scurf. The strength of the solution was then doubled and for another month the game went on, and that head is as it was. I am now about to apply the solution in the strength of one drachm to the ounce, this being the "strong blistering fluid" which, when diluted three times, forms the application that has worked such wonders for its discoverer. If this succeeds I shall be disposed to think that croton oil or any other "strong blistering fluid" would have done likewise, for it will be quite logical to conclude that the improvement will be due to the blistering rather than to the blister. One always instinctively views with suspicion any drug or means of treatment that has claimed for it powers that are at once extraordinary and widespread, and such, I must confess, was my attitude towards the biniodide treatment of ringworm of the scalp. For has not biniodide of mercury removed the dangers of scarlet fever during 1894? Has it not robbed influenza of its terrors, chronic diarrhœa of its inconveniences, children of their teeth grinding, and insects of their stings during the present year of grace?

I am, Sirs, yours faithfully,

Blackpool, Aug. 10th, 1895. LEONARD MOLLOY.

"CASTRATION FOR OVERGROWTH OF PROSTATE."

To the Editors of THE LANCET.

SIRS,—In your annotations (THE LANCET, p. 45, July 6th, 1895), in discussing the subject of castration for overgrowth of the prostate, you mention a paper which I recently read at the annual meeting of the American Surgical Association, and say thereof: "He had collected 111 cases of double castration by competent surgeons for enlarged prostate in extreme and exaggerated forms, which, he said, had 'resulted in cures.' All the same, he went on to show that twenty of these had died." Nothing in the paper, as read, as abstracted in the *New York Medical Record* (June 1st and 8th), from which you quote, or as published in full in "The Annals of Surgery" (July) justifies the statement that I said the 111 cases had resulted in cures. The next succeeding sentence in your annotation—"in 87·2 per cent. rapid atrophy of the prostate follows"—is sufficient evidence of the inaccuracy of the preceding paragraph, which I have quoted. I have endeavoured from the beginning not to make extravagant claims for this operation, and I shall be obliged if you will publish this correction.

I am, Sirs, yours faithfully,

Aug. 8th, 1895. J. WILLIAM WHITE.

*** We gladly insert Dr. White's letter. We said in our annotation that Dr. White showed that 20 of the 111 cases of double castration for prostatic overgrowth had died, and we were somewhat puzzled to know how this consisted with the statement in an earlier part of the report that "these cases, extreme and aggravated types, all by competent surgeons, had resulted in cures." We now see that these words are meant to apply to three cases, the histories of which were related as examples. We are sorry in any way to have misread the report of a very interesting communication.—ED. L.

OSTEO-ARTHROPATHY.

To the Editors of THE LANCET.

SIRS,—Your brief report of a case shown by me at the annual meeting of the British Medical Association at the Clinico-Pathological Museum contains a few statements which may mislead those who have not seen the case. It was a typical case of "pulmonary hypertrophic osteo-arthropathy" as differentiated by Marie from acromegaly. The hyperplasia is almost entirely bony, if we except the joints and the soft parts around the ankles. There is no lipping or alteration in the small details of the bone, the changes being massive in the affected parts. Although primarily a case of bronchitis and emphysema there is also some tuberculous consolidation.

I am, Sirs, yours truly,

Finsbury-circus, E.C., Aug. 13th, 1895. F. R. WALTERS.

"SPECIALISM IN MEDICINE."

To the Editors of THE LANCET.

SIRS,—The following information may assist you in answering the questions you ask in your recent leading article on the above subject. A few years ago, before I started practice, I met a friend whom I had lost sight of for some time and found that he had just consulted a well-known specialist for nasal obstruction, which he was anxious to get rid of before being ordained. Acting upon this gentleman's advice he was about to undergo an operation, and for that

Digitized by Google

purpose was to reside two or three weeks in a private hospital. The treatment, he told me, was to cost him considerably over £50. Knowing that he could ill afford the expense, and failing to see the necessity for such a lengthy course of treatment, or, indeed, for residence in hospital at all, I strongly advised him to disregard his appointments with the specialist and to consult a well-known general surgeon connected with a large London hospital. I afterwards learned from this surgeon that at two short sittings in his consulting-room he had done all that was required—viz., removed a nasal polypus and cauterised a hypertrophied mucous membrane. A few months later I met my friend again. He was very grateful to me, as the obstruction had been completely removed at the moderate cost of four guineas. Another very similar case occurred a few weeks ago in the practice of a brother medical man, to whom I am indebted for the particulars. Without his knowledge a patient of his had consulted a well-known specialist for nasal obstruction caused by a deflection of the septum. He had been told that for the necessary operation for its removal he must reside in a private hospital for at least a fortnight. His medical man, on being consulted, expressed his readiness to perform the operation in his consulting-room; but, finding that the patient was somewhat staggered at the marked difference with which the gravity of the operation was regarded by his two advisers, suggested that he should consult a third. Thereupon he consulted a general surgeon, whose name is well known in the profession, who operated in his consulting-room the same day, using cocaine, and sent him back to Wales the day following. The surgeon is still in ignorance that anyone else had been previously consulted. If you wish it I have no doubt I could supply you with the names and addresses of the patient's practitioner, surgeons, and specialist. As far as my experience goes, but it only extends to four years of private practice, probably the greatest abuse of the kind exists in connexion with the little operation for the removal of adenoids, which doubtless brings more grist to the special mill than any other. We all know that in the out-patient department of a London hospital the patient after this operation is generally sent home as soon as he has recovered from the anæsthetic, with instructions as to diet and to "come again next week." I am frequently hearing of patients being kept in a private hospital a week and even longer, of a nurse having been in continual attendance for the same period when the operation has been done in a private house, and of a staff of assistants having been present at the operation, and all this not necessarily in the case of wealthy patients, but of those out of consideration for whose slender purses the fee has been graciously reduced to twenty-five or thirty guineas. Now in these cases the fee is always proportionate to the fuss, and no one can possibly doubt that these methods of treatment, or at all events of after-treatment, are urged for any other than commercial reasons. As you say, we practitioners have it in our own hands to stamp out this bane of honest practice. If those who could were to make a point of attending the special departments of a large hospital they would soon find out how frequently they could dispense with the services of a specialist. Where this cannot be done we should in the end be the gainers by sinking petty jealousy and consulting each other more frequently. But above all, where it is desirable to obtain the best possible advice and the greatest skill, let us send our patients to a general surgeon or physician who in an out-patient special department has gained full experience in the so-called speciality, rather than to the man who spends all his time looking into an auditory meatus or observing three or four square inches of mucous membrane. By so doing we shall consult not only our patients' interests but also our own.

I am, Sirs, your faithfully,

July 29th, 1895. A GENERAL PRACTITIONER.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

The Recent Assizes: Crimes of Violence and Intemperance.

THE cases tried at the assizes which terminated on the 9th inst. furnish a very sad commentary on the efforts of humanitarians and philanthropists. The May assizes comprised a charge of murder of a most deliberate and aggravated character, being followed by the execution of the prisoner; and yet there were four charges of murder at the assizes held just two months later, none of them resulting in the capital conviction and sentence. In one case the prisoner cut his wife's throat while in a state of drunken frenzy, afterwards attempting his own life by cutting his throat. As is so often the case, the homicidal wound was instantly fatal, while the suicidal was less severe, and by skilful surgical treatment at the Northern Hospital the fatal issue was averted. In this, as in other cases of the kind, it is very probable that the prisoner was more drugged than drunk with the abominable adulterated beer sold in the lower parts of the city. It would be well if temperance advocates were to take note of this circumstance. Four men were charged with aggravated assaults on their wives, and three were sentenced to penal servitude for three years each, and the fourth to two years' imprisonment with hard labour. In one of these cases a conviction was obtained although the wife refused to say anything about the stabbing, while their son, aged twelve, who had in the first instance informed the police that he saw his father stab his mother with a clasp-knife, at the trial stated that it was a lie. Referring to the case mentioned in a former letter, in which a woman was charged with manslaughter in the case of a man who had died under the administration of chloroform, the prisoner was, at the instigation of the learned judge (Mr. Justice Cave), indicted for unlawfully wounding, and was sentenced to three years' penal servitude. A woman was sentenced to fifteen years' penal servitude for procuring abortion upon a woman who afterwards died, the judge ruling that the charge of murder could not be sustained.

Prevention of Cruelty to Children.

During the month of July the local Society for the Prevention of Cruelty to Children took up 112 new and 75 old cases, the former involving the welfare of 193, and the latter that of 101, children. Among the complaints were 3 of assault, 2 of excessive beating, 15 of ill-treatment, 155 of general neglect, 35 of begging by day, 12 of begging by night, selling after hours, exposure, sleeping-out, and dangerous surroundings. In 48 cases the parents were prosecuted and punished, in 82 cases the children were left with them subject to visitation, 169 parents were cautioned by the magistrates, and 65 by the Society. Nineteen children were committed to industrial schools.

The Holiday Season.

For many obvious reasons the August Bank Holiday is the most popular of all four. On the 5th inst. it broke all previous records in this city and neighbourhood, the crowds at the different railway stations and ferries exceeding by thousands those of any preceding year. It is very satisfactory that, notwithstanding this circumstance, there were no serious accidents reported. The holiday season here begins in July and is well advanced now, the various steamers to North Wales, the Isle of Man, Scotland, Belfast, and elsewhere being very busy. Season tickets are granted on most advantageous terms, and may be recommended as very good health prescriptions. A very pleasant day may be spent on board the steamer on the passage to and from the Menai Straits, the passenger returning to Liverpool each day. The boat starts at 10.45 A.M. daily, returning about 7 P.M. Many persons have found this a most excellent means of recruiting their health. The voyage to and from the Isle of Man occupies from four to five hours; the island as a health resort is almost unrivalled, the accommodation in hotels and lodgings being ample. Another very healthy and favourite trip is from Liverpool to Leith and back, the boat calling at intermediate ports and enabling the traveller to witness the grand scenery of the west, north, and east coasts of Scotland; the trip occupies a fortnight.

The Attack on a Lad at Walton.

The unfortunate lad William Ireland, the son of a medical man at Walton, died this morning at the Bootle Borough Hospital from the injuries received last week at the hands, it is alleged, of Mr. O'Callaghan, Mr. Ireland's assistant.

Aug. 14th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Fire at Minto House, Edinburgh.

AT the end of last week a fire occurred in Minto House, Chamber's-street, Edinburgh, which is part of the Extra-mural School of Medicine. It has done considerable damage

Digitized by Google

to the building, but that can be easily repaired, but some of the things destroyed cannot be replaced. The greatest sufferer has been Dr. Halliday Croom, who has lost his entire museum, the collecting of his whole professional life. He lectures on midwifery at Minto House, and much sympathy is felt for him in the loss of his teaching appliances. Dr. Haultain has also lost some of his teaching appliances, but his loss is small compared with Dr. Croom's.

The Edinburgh Royal Infirmary.

At the meeting of the managers of the Royal Infirmary yesterday the quarterly accounts showed an expenditure diminished by £755 as compared with the corresponding quarter of last year. Mr. Walcot, who submitted the statement, assured the board that while there was this diminution in outlay the comfort of the patients and the efficiency of the institution had not been lowered in any way, and that the first duty of the management was fully recognised to be the care of the patients and the maintenance of the honour of the institution in the administrative as well as in the medical and surgical departments. This reduced expenditure must be regarded as most satisfactory, but it could not be expected that it should be unaccompanied by suggestions of "cheeseparing" in different departments. All sensible people will agree that the utmost economy consistent with the high position the Royal Infirmary occupies is the object to be aimed at by the management.

The late Dr. John Howie Carslaw.

Dr. Carslaw was one of the most prominent of the younger generation of Glasgow medical men, and his early death has been a painful shock to his many friends. He received his education, literary and medical, at Glasgow University, where he graduated as M.A. in 1882, M.B. (with honours) in 1886, and M.D. (with honours) in 1893. He also studied at several German universities. His clinical knowledge was acquired mainly at the Western Infirmary, the hospital associated with the university, where he was successively house physician and house surgeon, and ultimately one of the physicians to the dispensary or out-patient department. He had, moreover, an extensive experience of infectious disease, gained at the City Fever Hospital, Belvidere, where he held a resident appointment. Dr. Carslaw was on the editorial staff of the *Glasgow Medical Journal*, and contributed to it articles principally founded on his observations at the Belvidere Hospital. In his position as assistant to the Professor of Practice of Medicine he showed himself to be an able clinical teacher, and in various ways exercised much influence for good.

Aug. 13th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Rotunda Hospital.

AT a meeting of the governors and guardians of this hospital held on the 2nd inst. the office of consulting physician to the institution, rendered vacant by the death of the late Sir George Porter, was filled by the unanimous election of Sir Philip Crampton Smyly, Surgeon in Ordinary to Her Majesty the Queen in Ireland. A letter was read from her Excelleney the Countess Cadogan, stating that she would have much pleasure in visiting the hospital on Friday, Aug. 30th, for the purpose of declaring the new surgical wing open for the reception of patients. His Excellency the Lord Lieutenant also expressed his intention of being present on that occasion. This visit of the Viceroy and viceregal party to the Rotunda Hospital will be the first occasion on which the patronage of the new representative of the Queen in Ireland will be conferred on a charitable institution.

The Irish Pharmaceutical Society.

A number of prosecutions have recently been instituted by the Pharmaceutical Society of Ireland. Messrs. Fannin and Co. of Grafton-street, Dublin, a firm of the highest respectability, were first attacked, and pleaded guilty of having infringed the very stringent provisions of the new Act. Last week Mr. John F. Corcoran was summoned and fined, a mitigated penalty having been agreed to; and the same course was adopted in the case of Mrs. Barnes, the proprietress of a druggist's shop in Charlemont-street.

The Viceregal Household.

His Excellency the Lord Lieutenant has been pleased to make the following appointments to the Household and Staff:—Physician-in-Ordinary, Mr. Walter G. Smith, M.D.; Surgeons-in-Ordinary, Mr. Edward Hamilton, M.D., F.R.C.S. Irel., and Mr. Kendal Franks, M.D., F.R.C.S. Irel.; Surgeon to the Household, Mr. T. Nedley, M.D.; and Surgeon-Dentist-in-Ordinary, Robert H. Moore, F.R.C.S. Irel.

A Fatality after Tooth Extraction.

The death of Mr. George Horan, which followed the extraction of some teeth by a dentist, has recently caused some interest and speculation in Dublin. The operation was followed by hæmorrhage of such a character that all efforts to control it proved unavailing and the patient died on the second day. The absence of a coroner's inquest has been the subject of rather unwise comment in some of the local papers, but it would appear that all the usual measures, including intravenous saline injection, were employed by a competent surgeon, though without avail. The patient was doubtless a victim to hæmophilia, and the catastrophe unavoidable.

Another Case of Ptomaine Poisoning.

The Limerick poisoning case, in which virulent products of decomposition disseminated through a quantity of custard from a single discoloured egg proved poisonous to a large number of persons and fatal to four, has not yet been forgotten in Dublin. Many letters have been addressed to the daily papers asking for information as to the nature of what, to many of the laity, are novel and hitherto unsuspected sources of danger in connexion with ordinary foods. The term "ptomaine poisoning," is not well understood, and, indeed, became familiar to many persons here for the first time only a few years ago when our popular and well-known city analyst, Sir Charles Cameron, suffered most severely from that form of poisoning, caused, in his case, by portions of a turkey which he unwittingly ate after it had been kept too long. His case was fully reported in the *Dublin Journal of Medical Science* by his friend and medical attendant, Dr. Hawtrey Benson. The illness, which lasted in his instance for many weeks, was caused beyond doubt by a single dose of slightly or partially decomposed meat. Now, an egg contains, from the biologist's point of view, all the complex and notoriously unstable substances which constitute protoplasm and are essential to life. The toxicologist knows that from such bodies, decomposed and regrouped, all the most virulent and subtle of the so-called ptomaine poisons may have their origin. Acute poisoning by decomposed egg is not, therefore, a surprise to him. An instance of food poisoning of a less virulent and serious character has recently occurred in Dublin, and, although owing to the absence of any fatality the particulars have not been made public, the facts are worthy of mention. At a large educational establishment some eight persons partook of stewed rhubarb from a dish which had been kept for some days and the contents of which had undergone slight fermentation and decomposition. They all suffered from gastro-intestinal catarrh of a more or less severe character; in other words, they all presented the symptoms of irritant poisoning. Happily, they all recovered after some days and are now in good health. The lesson, however, from these cases should not be overlooked. It is obviously unsafe to use as food either animal or vegetable substances which in hot weather have shown even the first indications of decomposition.

Diphtheria at Castleblayney.

I regret to report an outbreak of diphtheria at Castleblayney, there being several patients at present in the fever hospital. Some time ago a very serious outbreak, chiefly affecting children, occurred in the southern part of the county of Monaghan.

Medical Fees in Dublin.

The Recorder of Dublin has, in the recent case of White *v.* Russell, expressed himself on the subject of medical fees in Dublin in a manner to which the medical men in this city decidedly object. A correspondent of the *Irish Times* of Aug. 6th makes the spirited remark that "no person in any way acquainted with the duties and responsibilities of the medical profession could think for a moment that any fee less than £1 for three visits could sufficiently remunerate a medical practitioner for the care and attention which he

Digitized by Google

should devote to his patients, the English fees quoted being insufficient in most cases to pay for the bare car hire incurred in visiting."

Public Health and Sanitary Work in Dublin.

Sir Charles Cameron's report on the public health of Dublin during the four weeks ended June 29th shows that there were 571 deaths within the metropolitan registration area, giving a yearly ratio of 21·27 per 1000 persons living; within the municipal area, or city, there were 439 deaths, giving a yearly ratio of 23·35 per 1000 persons living. On the northern side of the city the rate was 21·95 and on the southern side 24·62 per 1000 persons living. The death-rate from the seven principal zymotic diseases was 1·5 per 1000 in the whole registration district, and 1·9 per 1000 in the city. On the northern side of the city the rate was 2·1 and on the southern side 1·7 per 1000. The total deaths attributed to zymotic diseases in the city of Dublin were 48, including 8 from small-pox, 1 from measles, 3 from scarlet fever, 8 from whooping-cough, 2 from diphtheria, and 6 from typhoid fever. The death-rate from all causes was 2·4 per 1000 below the mean rate for the corresponding period in the previous ten years. The zymotic death-rate was 0·7 per 1000 below the mean rate. Small-pox did not decrease very much during the month, 43 cases being notified, as compared with 66 in May (five weeks). One conviction was obtained under the Margarine Act and six (of milk vendors) under the Food and Drugs Act. Some of the specimens of milk analysed were of very poor quality, but not sufficiently so to warrant a certificate for adulteration.

The Water-supply at Belfast.

It was reported at the usual fortnightly meeting of the water board on Aug. 8th that, notwithstanding the recent rains, they had 254,000,000 gallons of water less than at the corresponding period of last year. This was due to the long period during which no rain fell. Another feature was the constantly increasing number of new houses which had to be supplied with water. They had passed 81 new houses on Aug. 8th, and at a previous meeting they had 123. It was suggested that the public should use the water as economically as possible. There was still, however, a 124 days' supply, which would last the city until the winter wet weather set in.

Rabies in the Downpatrick District.

At a meeting of the Downpatrick board of guardians held on Aug. 10th the question of the increase of rabies in the union was discussed, and it was decided by a majority to decline to sanction the issuing of an order for the muzzling of dogs; but it was unanimously agreed to requisition the Government to increase the dog tax. I am afraid this is simply shelving the matter for the present.

The Battle of the Clubs at Cork.

Last week Mr. Lee, honorary secretary to the Cork Medical Association, received a communication from the Mayor requesting him to meet him (the Mayor) and also the Grand Master of the Oddfellows, the President of the Bakers' Society, and the President of the Young Men's Benefit Society for the purpose of discussing the dispute between the medical profession and the clubs with a view to an amicable arrangement being arrived at, which the Mayor anxiously desires. The conference took place, and the club delegates frankly admitted that the Cork profession had substantial grievances to complain of. However, as Mr. Lee explained that he had come through courtesy to the Mayor, but that he was not authorised to enter into negotiations, the Mayor stated that he would request the medical profession to send six representatives to confer with six delegates from the clubs, and he would undertake to preside at the meeting. I have no doubt the Cork profession will be quite prepared to discuss the situation with the clubs, and though, as sensible men, they may not assume an uncompromising attitude with regard to details, they will keep clearly before them the general interests of the profession and the fundamental principles which induced them to go into the fight.

An Illustrative Case.

A case has been partially investigated at the Police-court which throws a light on the action of the Cork clubs. A Mr. Carroll sued the secretary of the Irish National Foresters for £9 12*s.* which he claimed as sixteen weeks' sick pay. According to the statement of his solicitor he became ill early in January last and complained of cough, vomiting, and sore-throat. He went to the club medical officer, Mr. McLoughlin, who attended him from January to the beginning of April and treated him for dyspepsia, but as he was not improving he consulted a non-society medical man. The latter told him he was suffering from a grave lung disease and recommended him to give up his employment. Next day he saw Mr. McLoughlin and explained that he had seen a non-society medical man. Mr. McLoughlin then told him he had congestion of the lungs and promised him a certificate of unfitness for his employment. Later Mr. McLoughlin stated that he had handed the certificate to the Wood-ward, but that the latter would not receive it because the complainant had gone to a non-society medical man. Mr. Carroll thought it time to consult a solicitor, and in reply to a letter from his solicitor the following copy of a resolution was received:—"Resolved—That in consequence of Brother David Carroll having, during his illness, refused to comply with the rules of the branch, and the instructions of the branch surgeon, and refused to be medicinally treated or prescribed for by him, we consider he has acted in violation of the rules of the society, especially as the doctor under whose care he is at present refuses to act in consultation with the medical officer of this branch. We, therefore, declare that Brother Carroll has forfeited all claims on the funds of the Branch.—Brother Sheares." Mr. Carroll gave evidence in support of his claim, and the case is still under investigation by the magistrates.

(FROM OUR OWN CORRESPONDENT.)

Antitoxin and its Results.

PROFESSOR RICHET publishes in the *Revue Scientifique* some figures which speak eloquently in favour of the new treatment of diphtheria. Any impartial observer who reads the appended table will acknowledge that either the disease has during this year (1895) assumed a milder type—an unwarranted assumption in my opinion—or that Dr. Roux's serum has proved a blessing.

Throughout his communication Professor Richet adopts a new spelling of the word *diphtérie*, which he writes *diftérie*. This is another attempt to forward the views of an influential party whose aim it has been for some years past to reform the orthography of a great many words in the French vocabulary. It is also a sign of the times that the *Médecine Moderne* informs its readers that it has printed the word *diphtheria* for the last time, and that it will in future adopt Professor Richet's spelling. It will, however, take some time to reconcile the medical world to this innovation.

Door-plates.

Visitors to Paris cannot fail to be struck with the absence of brass plates on the doors of the residences of medical men. As a matter of fact, a door-plate is considered *infra dig.* by our conservative French brethren. The only approach to our familiar door-plate that is tolerated is one bearing the

Digitized by Google

words "Docteur-Médecin." It would appear that the keenness of competition impels some practitioners to affix to their doors plates of greatly increased dimensions, some going to the length of adopting a sign suspended from their balconies or windows. This flagrant dereliction from professional dignity has evoked a protest from a member of the Syndicat des Médecins de la Seine, who brought the matter before his society at its last meeting.

The Continental Anglo-American Medical Society.

This useful society, which comprises almost all the British and American practitioners settled on the continent of Europe and in North Africa, held its annual meeting for the first time since its foundation (in 1889) out of Paris, the presence of so many of its members in England during the British Medical Association week having decided the choice of London as a place of reunion this year. About forty members assembled at the Savoy Hotel on Friday, Aug. 2nd, under the presidency of Sir Richard Quain, Bart., M.D., F.R.S., one of the society's most honoured honorary presidents. Five new members were admitted, these gentlemen hailing from Gibraltar, Tangier, Paris, Monte-Carlo, and Boulogne-sur-Mer. Dr. Barnard (the honorary secretary and treasurer) stated that the actual number of members amounted to ninety-six, and that every recruit at Continental health stations appeared anxious to join. A luncheon followed at the same hotel, the chair being again taken by Sir Richard Quain, whose genial toast, "Prosperity to the Society," was highly appreciated and loudly cheered. The company numbered fifty-four. Dr. Barnard (362, Rue St. Honoré, Paris) will supply any information regarding the society to any inquirers. I may mention in conclusion that it has been decided to hold the next annual meeting at the same time and place as the British Medical Association. Oxford is, I am informed, the *locus* selected.

ROME.

(FROM OUR OWN CORRESPONDENT.)

Fatal Coincidences.

IN a recent annotation in THE LANCET on "Alpine Misadventure"[1] a remark was made on the fallacy to which the classification of death-causes is liable, when, as in the case of Baron Peccoz, who was officially reported as "killed" on the Lysjoch last August, it turned out that he really "died" from syncope antecedent by a few seconds to his so-called "fatal slip" on the verge of the crevasse. But for the syncope, in other words, he would have kept his balance and extricated himself from the position in which he found himself—a position not more perilous than what he, a trained Alpine pedestrian, was habitually courting. A not less striking coincidence, in confirmation of that remark, has been reported from Turin, not far from where, at the Camp of Lombardore, during recent military evolutions, Lieutenant Tapparone was accused of having caused the death of the soldier Morfeo. Both officer and private belonged to a cavalry regiment, and it was alleged that the former, irritated by some *gaucherie* on the part of the latter, seized him violently, shook him off his horse, and killed him by the fall. Ever eager to find those in authority abusing their power, the "advanced" lay press was dilating on the brutality of Lieutenant Tapparone, and invoking public sympathy for his victim, when at the instance of the War Minister an inquiry was held on the whole case. It was established by cogent evidence, including eye-witnesses among Morfeo's comrades, that he was in no way violently handled, that he was not "pushed," but lightly touched, and that he actually "fell" from his horse; while by those who were his intimates he was known to have been for some time seriously out of health. On post-mortem examination there was found no trace of external lesion, but a very diffused cadaveric ecchymosis. The lungs were sound; but the heart was completely empty, having ceased to pulsate during the last systole. In the abdomen there was no extravasation of blood or serum; there were, however, marked intestinal adhesions—one, particularly pronounced, of the liver to its diaphragmatic vault, the result of an inflammation which had run its course in youth. No other viscus presented any abnormal feature; the brain also was healthy, without trace of apoplectic lesion. The medical report, in accordance with the necropsy, was, therefore, "il Morfeo è morto di sincope cardiaca." The syncope was, in fact, coincident with, or, more properly, immediately prior to, the fall from the horse—the final link in a chain of antecedent malaise. Lieutenant Tapparone was congratulated (and with every reason) on his narrow escape from a charge of manslaughter—a charge in which "appearances" were strongly against him till the medical finding put the matter in its true light.

[1] THE LANCET, July 20th, 1895.

A Centenarian Surgeon.

At Pesaro, on the Adriatic, Dr. Giacomo Asiari attained his hundredth year on the 29th ult., and a brief biography of him has just been issued by a local colleague, Dr. Carlo Rigoni, with the twofold object of putting on record the career of an interesting professional man and of establishing, subject to every available check, yet another *bonâ-fide* instance of a centenarian. Dr. Asiari was born at Forlì on July 29th, 1795, at noon. He studied at Forlì, Faenza, Ravenna, and Florence, at which latter school, on June 17th, 1821, he received his diploma in medicine and surgery. In 1823 he was called to Spoleto as "chirurgo primario" in the hospital there, and distinguished himself as an able and successful operator. His next appointment was in the University of Macerata, where he filled the post of "chirurgo primario" and reader in human anatomy. This readership he succeeded in getting transformed into a regular chair of anatomy, founding, indeed, a "scuola di anatomia" which was previously non-existent in that seat of learning. In 1829 he was called to Pesaro, once more as "chirurgo primario," and there his clinical duties and the calls of an ever-increasing *clientèle* kept him actively employed for the next thirty years, during which he took rank with the leading men of the city and province, like Count Cassi, Baldassini, Paoli, Petrucci, and Perticari. He attended, among other distinguished patients, Prince Charles Buonaparte when, in company with his brother Louis (afterwards Napoleon III.), the Prince in alighting from his carriage had gravely injured his knee. In the cholera year of 1855 he rendered invaluable service to the poorer victims of the disease, for which the Pesarese town council awarded him the gold medal of merit. Finally, in June, 1861, he went on the retired list, and the town council, in recognition of his merits as a surgeon and as a citizen, gave him a life pension equal in amount to the salary he drew in office. Dr. Asiari therefore made over his "armamentarium chirurgicum" to the San Salvatore Hospital and his fine medical library to the Bibliotheca Oliveriana. Since then he has enjoyed a serene and honoured old age, his one complaint being the intercurrent neuritis to which he has been subject for seventy-eight years.

Heat and Venomous Bites.

The prolonged sultry weather has added many more to the instances recently adduced of the virulence it imparts to the bites of venomous animals. The last one medically reported is that of a poor woman of Borgotaro, in the province of Parma, who, after working in the hayfield and partaking of a hearty meal on the spot, was bitten by a viper. She was attended to without loss of time, and the surgeon freely excised the seat of the bite and its immediate surroundings; but swelling rapidly set in, the cutaneous surface as a whole became a livid colour, and in barely ten minutes the patient died in agonising convulsions. Nor is it the venomous reptilia only whose poison is intensified by the more than subtropical heat we have lately been having. In the lake country, at Valmadrera, near Como, a deaf-mute was stung by a fly supposed to have been in previous contact with an animal affected with anthrax. The local inflammation soon became general, and after a day's excruciating pain, during which the unfortunate victim moved the compassion of all by his inability to describe his sensations and explain his wants, death supervened as a welcome relief. Flies, it is well known, exert a depurating function on the air, and when this becomes charged with noxious effluvia exhaling from freshly manured fields they imbibe enough to make their stings dangerously poisonous. The hotter the weather the more virulent the sting. In Switzerland, for example, where the practice of treating the freshly upturned earth with liquid manure is general throughout the summer,

Digitized by Google

the effluvia thence arising under exceptionally sultry days renders a walk or drive along her picturesque highways and byways a very chastened joy indeed. Not only so, but the common horse-fly in these circumstances becomes a formidably aggressive poisoner. Not so long ago at Thun a lady was stung under the lower eyelid by one of these winged tormentors, and in less than an hour such swelling and pain set in that nothing short of the best surgical interference, telegraphed for from Berne, succeeded in saving her life.

Professor Maragliano.

The interest aroused in Professor Maragliano's treatment of phthisis, as submitted to the British Medical Association, has extended to France. At the Congress of the Société de Médecine, which, under the presidency of Dr. Bouchard, opened its proceedings last week at Bordeaux, Professor Maragliano has been vouchsafed an entire sitting for the exposition and discussion of his views. Before leaving London he was, I may mention, "interviewed" by the representative of that widely diffused journal *Il Secolo*, to whom he expressed his high admiration of the sanitary institutions, the hospitals, and the whole hygienic organisations of the British capital. He was surprised at the solidarity prevailing among the British medical men, at their well-disciplined meetings, at the practical sense which guides them, not only in the field of science, but in that of professional interests. The admirable organisation of the meeting itself elicited his special commendation, its hospitality being "superiore alle speranze anche degli esigenti" (beyond the hopes even of the exacting). The scientific discussions he found impressed with the gravity proper to the practical genius of the race, and while he missed the enthusiastic outburst of his southern compatriots he remarked the "molta attenzione nel seguire le discussioni e le communicazioni scientifiche" (great attention in following the scientific discussions and communications).

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

Ménière's Disease.

PROFESSOR MAX GRUBER, at a recent meeting of the Vienna Otological Society, read a paper on Ménière's Disease. Ever since the attention of pathologists was directed to this disease and quinine was recommended by Charcot as a valuable remedy against it the recognition of it has been easy if vertigo, tinnitus aurium, and deafness are present. It has been proved that the vertigo results from disease of the semicircular canals. Ménière's disease may, however, according to Professor Gruber, be caused by secretory and exudative processes as well as by a hæmorrhage. Pigment originating from an extravasation may be found in the sacculus, cochlea, and semi-circular canals in the ears of persons who during life never suffered from vertigo. On the other hand, the aquæductus cochleæ, and especially the recessus Cotunnii, into which the aquæductus vestibuli discharges itself, must not be overlooked. This recessus varies greatly in size; sometimes it is hardly to be found, sometimes it is as large as a bean. The membranes of the recessus may be united by connective tissue, and then a lymph engorgement takes place, which produces an abnormal pressure and extravasation of blood, and consequently Ménière's symptoms. A too free use of alcohol may also give rise to these symptoms, because the secretion of lymph is increased in consequence of the determination of blood to the head. Professor Gruber proposed to restrict the name Ménière's disease to phenomena originating in the labyrinth and to separate it from feverish conditions such as labyrinthitis.

Asepsis and Antisepsis in Ophthalmology.

Ever since Gayet showed by his experiments that out of 178 inoculations of eyes cultures resulted in 139 cases and failed only in 39 cases, it has been recognised that an absolutely antiseptic condition of the conjunctiva is not to be obtained; the infective action, however, is limited to those micro-organisms which adhere to the surface of the epithelium. As corrosive sublimate produces opacity of the cornea, and some other remedies become decomposed or have a disagreeable odour, Dr. Grossmann in the *Therapeutische Wochenschrift* recommends cyanide of mercury. It has been employed by Chibret, and possesses the same bactericidal quality as corrosive sublimate, without irritating the tissues or coagulating albumen in such a marked degree as the latter. A solution of 1 in 5000 is sufficiently strong, but it must not be used when the capsule of the eyeball is to be opened, for if it penetrates into the anterior chamber of the eye it may injure the endothelium. Eye washes, as a rule, contain germs of micro-organisms even when prepared with distilled water. Dr. Grossmann therefore adopts Franke's proposal to make use of a solution of corrosive sublimate (1 part in 10,000) for the purpose of dissolving the salts of atropine, cocaine, and eserine; he also recommended frequent sterilisation by boiling.

The Effect of Compressed Air on the Health of Workmen.

In the issue of THE LANCET of July 6th I mentioned some cases of the so-called caisson disease produced by compressed air. The Council of Hygiene requested Professor Max Gruber to prepare a report on this subject, and he has now made the following recommendations: (1) the ventilation is to be improved with a view to diminish the carbonic acid contained in the air of the caissons; (2) a time of from seven to ten minutes is to be allowed for the entrance of the workmen; and (3) a permanent medical service is to be established, the medical officer of which shall satisfy himself as to the gradual condensation of the air. Dr. Silberstein has published an interesting article on Caisson Disease in the *Medicinische Wochenschrift*, mentioning the loss of control over the lower extremities, the urinary bladder, and the rectum as being by far the most important symptoms. He suggested the presence of nitrogen in the spinal cord, which, when the pressure becomes lowered to that of the external air, forms gaseous vesicles in the blood, and by obstructing the vessels produces the above-enumerated paralyses. Not uncommonly patients suffer also from vertigo, increased knee-jerks, and crackling in the knee-joint due to the pressure of gas liberated in the cellular tissue.

Death of Dr. Bettelheim.

By the death of Dr. Bettelheim, who passed away on July 26th, the medical profession in Vienna has lost one of its most able representatives. Born in Pressburg (Hungary) in 1844, he studied at the Vienna School of Medicine under Hyrtl, Rokitansky, Skoda, and Brüke, and after having obtained his diploma in 1866 he acted as assistant to the late Professor Oppolzer. In 1873 he was recognised as *privat-docent* in Pathology, and during the succeeding eight years edited the *Medicinisch-Chirurgische Rundschau*. Among his numerous published works I need mention only those on "Pneumonia Biliaris," "The Diagnosis of Cancer of the Stomach," and "The Use of Muriatic Acid in the Treatment of Gastric Diseases." Dr. Bettelheim felt himself slighted because he did not succed in obtaining an ordinary professorship; during the last five years he was Primarius of the Rudolfinerhaus.

CONSTANTINOPLE.

(FROM OUR OWN CORRESPONDENT.)

Granular Ophthalmia.

AT the last meeting of the Imperial Society of Medicine Dr. Malgat of Paris delivered a very interesting lecture on Granular Ophthalmia. A good many members attended, notwithstanding the very hot and oppressive weather which prevails here just now. Dr. Malgat first of all referred to the treatment of granular ophthalmia amongst the ancient Greeks and the Egyptians, and then enumerated the various methods that have been adopted up to the present time, showing that they were all inefficacious and dangerous. He then fully described the treatment by electrolysis. After demonstrating that the proposed cures by conjunctival cicatrices formerly recommended were not without danger for the patients, he declared that among fifty cases treated by the electrolytic method he had seen fifty complete cures without any cicatrix whatever, just as if the conjunctivæ had never been diseased. The practical application of electrolysis is neither painful nor complicated; on the contrary, it is wonderfully simple and does not involve the slightest danger to the eye. The apparatus used for the purpose is in the hands of all practitioners, being simply a

Digitized by Google

small Gaiffe's continuous current battery of seven pairs. Dr. Malgat uses negative electrolysis. In order to make sure of success it is necessary to follow the granulations everywhere, even into the cul-de-sac of the upper eyelid, and for this purpose it will often be necessary to make a small incision into the conjunctival cul-de-sac. Dr. Malgat always prefers this last method. At the conclusion of the meeting he was unanimously nominated a corresponding member of the society.

Cholera.

The epidemic has not quitted our country, but is slowly spreading in several provinces in the interior. The latest telegrams announce an outbreak of the disease in the provinces of Maamuret-ul-Aziz and Adana. At one of the villages in the former province no fewer than twenty-seven cases of cholera, with six deaths, occurred between July 20th and 22nd. Sporadic cases are reported from several villages in these two provinces.

Quarantine.

The General Board of Health decided at its meeting on July 22nd that arrivals from the littoral between Alexandria and Suedieh shall be subject to a quarantine of five days; vessels without passengers need not, however, remain in quarantine longer than twenty-four hours. The quarantine measures against arrivals from the Karamanian coast are maintained.

July 26th.

NEW ZEALAND.

(FROM OUR OWN CORRESPONDENT.)

A GENTLEMAN who seems to have devoted a certain portion of his leisure while in America in the direction of medical study, made a very sturdy attempt recently to compel the Registrar-General in Wellington to have his name placed on the list of recognised medical practitioners; in fact, Mr. Justice Richmond paid a high compliment to the applicant's counsel for the exceedingly able manner in which he had argued his case. Now, as a matter of fact, we have quite enough legalised medical practitioners in New Zealand at the present time without semi-qualified persons attempting to have their names enrolled on the list; indeed, it is only too true that the number of medical men coming to reside in this colony has increased very considerably of late. I fear many are disappointed with the general results attending their emigration here, for New Zealand is amply provided for in the way of medical men even unto the humblest country village. These remarks are penned in the hope that disappointment in the future may be saved, for New Zealand is not now the Elysium that it was for the medico. When the colony was in its infancy persons holding almost any kind of qualification were recognised as medical men, but times have changed since then, as the applicant has now discovered, for his request was emphatically refused by Mr. Justice Richmond, whose judgment will, let us hope, deter others from emulating such an example.

Obituary.

STEPHEN JENNINGS GOODFELLOW, M.D., F.R.C.P. LOND.

STEPHEN JENNINGS GOODFELLOW was born in Falmouth on Oct. 21st, 1809, his mother having come over from Portugal for her confinement, and returning to that country with him in the early part of 1810, his father, a member of an ancient Northamptonshire family, being then a merchant resident at Lisbon. They returned to England before the Peace of 1815, as Dr. Goodfellow remembered the illuminations at Falmouth on that occasion. His family were not greatly in sympathy with intellectual pursuits, but even as a very young man he showed marked ability, reading such works as "Locke on the Understanding," &c., for the pleasure of the intellectual exercise. He was very anxious to go either to Oxford or Cambridge, but, his father not being alive to the advantages of a university education for him, he was unable to go and therefore most gladly availed himself of the opportunities given by the establishment of the University of London. There he passed his examination as rapidly as possible. He has often described the difficulty of the *viva voce* in those early days, students passing from one table to another to be examined in six different subjects before quitting the examination room. He was an enthusiast in his profession, devoting many hours to its study, and when attached to the London Fever Hospital he often pursued his studies far into the night, once or twice being overtaken with sleep in the post-mortem room. He was particularly neat and skilful in his preparations of microscopic objects, and many of his preparations still exist in the museums of the Royal College of Surgeons of England and the Middlesex Hospital. He married in 1846 Elizabeth, the daughter of William Nanson Eyre of Carlisle. She took great interest in his scientific work, assisting in the translation of foreign works and helping in drawing diagrams and sketches to illustrate his lectures. He had a particularly happy method of teaching, as many of the old students who studied under him must remember. Everything was presented to the mind with great clearness and in an interesting manner. Even in his practice he made his patients understand the reason of much of his treatment, and was particularly successful with nervous and hysterical patients. He had at one time a large connexion in America, and many and urgent invitations were sent to him to visit Boston and other parts; and, though he never went over, many persons came from America on purpose to consult him. When he settled in London after his marriage he was one of the founders of an observation society, to which some of the subsequently leading members of the profession belonged. The members of this society met at each other's houses at stated intervals for the discussion of interesting cases and scientific facts.

Dr. Goodfellow was educated at grammar schools in Cornwall, the last one being the endowed school at Bodmin; his early professional education was under the superintendence of a gentleman in large general practice at St. Austell; in October, 1830, he entered at St. Bartholomew's Hospital, and in 1832 became a Member of the Royal College of Surgeons and a Licentiate of the Apothecaries' Company. He did not enter into practice until 1834, but from a dislike to general practice became a candidate for, and was elected to, the posts of resident medical officer and superintendent of the London Fever Hospital. On the establishment of the University of London he obtained at the first examinations under the Charter the degree of M.B., and the following year that of M.D. In 1841, at the request of Mr. Skey, he consented to join him in the lectures on general Anatomy and Physiology at the Aldersgate School of Medicine, especially that part relating to the minute anatomy of muscle, skin, and mucous membranes, to which he had for some time given special attention. Shortly before the commencement of the winter session Mr. Skey was appointed lecturer on Anatomy and Physiology at St. Bartholomew's Hospital, and Dr. Goodfellow in consequence was urgently requested by the other lecturers to take the whole course, to which he reluctantly consented. About this time he translated for the *Microscopical Journal* Gruby's thesis on the "Morphology of Pathological Fluids," and on the death of the editor of that journal was appointed to fill his place. As a result of a consultation with the publisher, Mr. Van Voorst, and several persons who took a warm interest in the use of the microscope as an important instrument in anatomical investigation, it was deemed desirable to enlarge the objects of the journal and to give it a more special designation. In furtherance of this view it was published under the name of the *London Physiological Journal*, Dr. Goodfellow and Mr. Edwin Guckett, the lecturer on botany at the London Hospital, being the editors. Several important papers were published in successive numbers by Dr. Carpenter, the editors, and others. Among other papers was included one by Dr. Goodfellow on the minute structure of voluntary muscle, with careful drawings, confirming for the most part the views of Dr. Todd and Mr. Bowman. In 1840 he discovered, by $\frac{1}{18}$ object glass, moving bodies (animalculæ) in the blood of a patient suffering from typhoid fever, and sent a description of them with accurate measurements by the micrometer eyepiece to the *Medical Times and Gazette*. These bodies closely resembled, if they were not identical with, those now known as bacilli. In 1844 he was elected to the post of honorary physician to the Cumberland Infirmary, and, resigning his office at the Fever Hospital, took up residence at Carlisle. But in 1846, finding that the practice was never likely to come up to his expectations, and with a large and influential connexion in

Digitized by Google

London, he gave up the appointment, and returned to London and settled in a short time in Russell-square.

In 1847 he became a Member of the College of Physicians, and, as a remarkable fact, out of the five candidates who went in for the membership three—Dr. Stewart, Dr. Frere, and Dr. Goodfellow—soon after became attached as physicians to the Middlesex Hospital, although previously quite unacquainted with each other. In this year also he was elected physician to Aldersgate Dispensary and lecturer on Medical Jurisprudence and Toxicology at the Middlesex Hospital, and in 1849 received the appointment of assistant physician to the hospital. In 1851 he was elected to the Fellowship of the Royal College of Physicians, and on July 15th, 1858, became full physician to the hospital, and on the resignation of Dr. Seth Thompson and Dr. Crawford he was appointed lecturer on medicine jointly with Dr. Stewart. On the retirement of Dr. Stewart he gave the whole course on medicine. In 1860 he removed to Savile-row. In March, 1869, he had a threatening of paralysis. He had given his usual systematic lecture from 9 to 10, and after his morning's occupation at home returned to the hospital for his regular visit, and had given several clinical demonstrations in the wards. After being some time in the post-mortem room, while examining some diseased tissue under the microscope, he was seized with giddiness and loss of power in the left leg. In a short time this went off, and he was able to accompany his resident house physician to the female ward to prescribe for the worst cases, intending to walk home and send his butler round to countermand his engagements; but, on reaching the hospital gate, he met his carriage, and on arriving at Savile-row he found the left leg again partially paralysed. This altogether disappeared on the following day. This led him to regard it as an emphatic warning and to give up the lectureship at the end of the session, and soon after the office of physician, and gradually to withdraw from practice—a step, it is needless to say, requiring very long and anxious consideration. There is every reason to believe that to this important step, although at the cost of giving up a very lucrative practice, he owed his complete recovery and the enjoyment, with a few trifling exceptions, of perfect health up to a little over two years ago, when his life was almost despaired of, owing to an attack of influenza; he had also the great grief of losing his wife by the same disease. For some time after that attack he was in a low state—physical and mental—which led him to part with his residence in the neighbourhood of Dartmouth and remove to Paignton, where he regained his health to some extent, but he never really recovered, and passed away on the 19th ult. at the age of eighty-six.

FREDERICK ALBERT HESLOP, L.R.C.P., F.R.C.S. EDIN.

MR. FREDERICK HESLOP died on the 2nd inst., after a short and painful illness, from an attack of pleuro-pneumonia contracted in the course of his professional duties, and it seems probable that had he thought more of his own safety than of the welfare of his patients he might have escaped his fatal illness, which followed a long journey in wet clothes to a poor woman's bedside. He was devotedly attended by Mr. Vinter, his assistant, and his brother, Mr. William Heslop, who had the services of Dr. Kingsbury and Dr. Graham Steell in frequent consultation; but a constitution which was undermined by much previous sickness was no match for such a disease as his last. Frederick Heslop was the son of the late Dr. Robert Heslop, whose name was so honourably associated with the early days of St. Mary's Hospital, Manchester; and his uncle, Dr. Ralph Heslop, was one of the leading practitioners in Preston. He himself gave much promise of a brilliant career. He was one of the surgeons to the Blackpool Hospital and had a seat on its board. He also filled the post of surgeon to the police force and to the fire brigade of Blackpool, and was an examiner for the St. John Ambulance Association, in whose work he took the keenest interest. He had recently been president of the Fylde Medical Society. Cut off at the early age of thirty-seven, he leaves a widow and three children. Mr. Heslop had won the esteem of his medical brethren by his many good qualities; he was a trusty friend, sincere and straight, and his short life had been long enough to gain him the respect of his townsmen and to set an example of unselfish devotion to duty. The profession is not lacking in illustrations of the dangers of its members, or their willingness to meet them, and the name of Frederick Heslop may fairly claim a place in the list of medical martyrs.

THE BRITISH MEDICAL ASSOCIATION.

MEETING IN LONDON.

THE SECTIONS.

MEDICINE.

FRIDAY, AUG. 2ND.

The Causes of Acute Rheumatism, and its Relation to other Affections.

Dr. CHEADLE, consulting physician to the Children's Hospital, Great Ormond-street, introduced the discussion on this subject in an able and exhaustive paper, with the main conclusions of which the majority of subsequent speakers agreed. He laid stress on the fact that it is a general disease, of which arthritis is but one of many symptoms. The diseases which are regarded as rheumatic were then reviewed as purpura rheumatica, subcutaneous nodules, endocarditis, and chorea. The cardiac affection of chorea was probably rheumatic, it being organic, and endocarditis being the most constant change in fatal chorea. Pericarditis and endocarditis were almost exclusively rheumatic, and so were the exudative erythemata. Rheumatism was the only general disease having an association with chorea, except scarlet fever; and scarlatinal chorea and endocarditis were almost certainly rheumatic, as was also the chorea of pregnancy. The general argument in favour of the rheumatic nature of chorea was very strong, as the alternation of the two diseases in successive members of the same family shewed. The seasonal and annual curves of prevalence of the two diseases were identical, as shown by Lewis in Philadelphia and by Newsholme in London. The association of various phenomena, such as endocarditis, chorea, erythemata, and subcutaneous nodules, formed a diagnostic feature of rheumatism. Subcutaneous nodules almost disappeared with the advent of puberty; and chorea and endocarditis similarly became less common with advancing age. If the picture of rheumatism had been drawn from its manifestations in childhood arthritis would not have been taken as its characteristic phenomenon. In addition to the direct morbid agent producing rheumatism certain other factors were important. Chill was a common factor, though not a constant one. Rheumatism appeared to prevail most in winter and spring. Dr. Newsholme's exhaustive researches, given in the Milroy Lectures this year, showed that it was most prevalent in dry seasons associated with a low subsoil water and an unusually high soil temperature. This was not incompatible with the action of chill as a factor in the disease. The influence of hereditary tendency had been underrated rather than overrated, and could not be explained by the influence of locality or personal association. Evidently some general systemic influence was at work in producing rheumatism. This was a toxæmia rather than a neurosis. The toxæmic agent was not uric acid (Haig) or lactic acid (Prout), or these together (Latham). The arguments in favour of a micro-organism invasion had been forcefully given by Dr. Newsholme. All the varied phenomena of the disease suggested an infective disease. It was objected to this view that there was no exact period of incubation, that the evidence of direct infection was rare and doubtful, that the specific organism had not been discovered, and that the disease had not been produced in man by inoculation. The organism would probably be found to be analogous to that of pneumonia, tetanus, or tubercle, rather than to those of the more infectious diseases.

Sir DYCE DUCKWORTH accepted the infective theory to a modified extent, having somewhat changed his views on this point. It did not, however, explain all the productive factors of rheumatism. Probably the exact proof of the infective theory would be shortly forthcoming. Other factors were required. A diathetic disposition is necessary, which is transmissible from parent to child. This affords a soil for the disease. It is probable that some persons never could have rheumatism. It was only predisposed persons that, under conditions of lowered vitality, became the prey to some micro-organism which germinates in the blood, developing a toxine therein.

Dr. A. GARROD remarked on the absence of foundation on which the lactic acid theory stood. The synthetic evidence of Richardson and Foster was equally dubious. There could

Digitized by Google

be little doubt as to the infective nature of the disease; but the long continued course, and the way in which the disease crops up like malaria, were more analogous to syphilis than to an acute infectious disease. He suggested that chorea might be due to a poison produced by the rheumatic fever organism and thus be analogous to post-diphtheritic paralysis. The temperature curve of rheumatism varied with the local manifestations. There was no definite temperature curve even when salicylates were not given.

Dr. A. MANTLE referred to his paper on the Bacterial Origin of Rheumatic Fever published nine years ago. He quoted interesting instances of multiple cases in households, and of the association of the disease in the same house with scarlet fever, &c. Erythema nodosum he regarded as a distinct disease. He quoted Trousseau as thinking it was no more a variety of rheumatism than smallpox was of ecthyma. He had found cocci and bacilli in the joints and blood-serum of patients.

Dr. NEWSHOLME entered a preliminary objection against the use of the term "acute rheumatism," as this appeared to imply that chronic rheumatism was a variety of the same disease. It was a pity that the use of the word "rheumatism" for chronic troubles was continued. He maintained that clinical, pathological, and therapeutical considerations were strongly in favour of the view that rheumatic fever was a specific febrile disease. He had in the Milroy lectures collected evidence of the excessive prevalence of the disease at intervals of a few years. This evidence was based on hospital experience and death returns in this and other countries, and on the compulsory notification of all cases of rheumatic fever for thirty-three years in Scandinavia. In this country 1868, 1874–5, 1884, and 1888 were years of great epidemic prevalence. A comparison of the curve of prevalence of the disease in Christiania with that for the whole of Norway indicated a gradual spread of the disease. From ground water observations at Croydon and Brighton it was clear that the commonly asserted association of damp soil with rheumatism did not hold good. Rheumatic fever in these towns was always small in amount in years in which the ground water was high, and was usually excessive in amount in the years in which the ground water was low. Observations in London also showed that the four-foot earth temperature was exceptionally high in the years in which rheumatic fever was unusually prevalent. It remained for further observations to confirm or refute the above, but until a complete notification of all cases was obtained our knowledge of the natural history of rheumatic fever must necessarily continue imperfect.

Sir T. GRAINGER STEWART thought that the proper attitude of mind was one of suspense until the specific micro-organism of rheumatism was discovered. He attached no importance to the earlier work on the experimental pathology of rheumatism, and considered that the trend of facts was in favour of the specific febrile character of rheumatism. He supported Sir Dyce Duckworth's statement that a variety of morbid conditions were now included under the common name of rheumatism, and thought that differentiation was required as in the analogous case of diabetes. He was of opinion that rheumatism began as a local disease, and might remain so for days before infecting the whole system, giving an instance of rheumatism in the elbow-joint caused by prolonged leaning out of a carriage window, which only after several days spread to other joints. The practical rule was not to neglect local rheumatism.

Dr. H. HANDFORD was of opinion that any satisfactory explanation of the pathology of rheumatism must explain the affections closely allied to it. He instanced cases of rheumatoid arthritis beginning acutely, and only distinguishable from rheumatic fever by their refractory character. The progressive character of certain cases of endocarditis after the acute disease ends was not satisfactorily explained on a pure bacillary theory.

Dr. A. HAIG defended the view that rheumatism is due to the excessive introduction into and retention of uric acid in the system. This was unlike Dr. Latham's view, which implied the increased production of uric acid in the system. Sir A. Garrod's observation that no uric acid is found in the blood in rheumatic fever led him (Dr. Haig) to the opposite conclusion to that usually drawn from this supposed fact, as the uric acid had got into the joints. The bad effect of meat on rheumatic fever convalescents was explicable on the grounds that uric acid was thus introduced, and the salts of meat diminished the elimination of uric acid.

Dr. STEPHEN MACKENZIE agreed with Dr. Cheadle in shifting the standpoint of rheumatism from the adult to the child, and in regarding it as no mere arthritis. Referring to the point of nomenclature raised by Dr. Newsholme, he agreed that acute rheumatism was objectionable as connecting it with chronic rheumatism, and thought that objection might be taken against any other name. He pointed out that in several other microbic diseases no microbe had been found. The local commencement of symptoms emphasised by Sir T. Grainger Stewart did not necessarily imply a local origin. If Dr. Haig's view was to be accepted he could not understand the inefficacy of salicylates in gout or the infrequent concurrence of rheumatism and gout in the same person. He regarded chorea as essentially rheumatic. The non-effect of salicylates did not negative this view, as the same applied to exudative erythemata. The difference between the tissues affected might explain this.

Dr. D. B. LEES believed that erythema nodosum was a distinct disease, as much as scarlet fever or measles, having a definite eruption and duration, and, from his experience, no second attacks. The occasional loss of knee-jerk in chorea was not explicable on the neurotic or fright theory. It was probably due to a blood poison and analogous to the loss of knee-jerk in diphtheria. There was further evidence of a blood poison in the acute dilation of heart seen in pericarditis, which, in the light of Gaskell's researches, was probably not due to the pericarditis itself. He suggested the analogy of diphtheria and of tetanus, in which a local multiplication of micro-organisms occurred, and a general poisoning of the system by a toxine. If so it might be possible to attack rheumatism locally in the throat.

Surgeon-Lieutenant LONGHURST thought that constitutional considerations were in danger of being overlooked and could not accept the germ origin of rheumatism. He had observed rheumatism in India and Africa, and had not seen it in warm and dry climates, but it developed after a few days of fog and rain. Statistics were, in his opinion, misleading, because they did not take into account the waves of atmospheric influence.

Dr. CHEADLE, in replying, said that he had given large doses of lactic acid to patients, but with negative results. He could not agree that erythema nodosum was a disease distinct from rheumatism. He agreed with Dr. Newsholme's objection to the use of the phrase "acute rheumatism," but thought that a new term was desiderated. He was much interested in the evidence of slow spread of the disease in Norway, whether this meant personal infection or infection of localities. The refractory cases mentioned by Dr. Handford probably had a different pathology to rheumatism. Unlike Dr. Lees he certainly had seen the coexistence of rheumatic fever and erythema nodosum.

SURGERY.

THURSDAY, AUG. 1ST.

The Treatment of Ulcers and Alopecia by Oxygen Gas.

An interesting series of cases were exhibited on Thursday in Room No. 30 of King's College by Mr. George Stoker, illustrating the effects of the local application of oxygen. In all the cases the disease had existed for a long time and had resisted every other method of treatment. The general mode of application was by enveloping the part affected in an indiarubber bag modified in shape according to the portion of the body to be covered. This bag was supplied through an indiarubber tube from a larger bag, which latter was filled once in twenty-four hours and acted as a reservoir to supply the other by its own elasticity. When the surface of the skin was broken the oxygen was mixed with an equal quantity of air purified by passing it through a solution of permanganate of potash and chloride of calcium. When applied to an unbroken surface, as the head for alopecia, pure oxygen was used. The cases included: 1. a woman seventy-one years of age with a large callous Ulcer of the Leg. Every available method of treatment had been tried, including antiseptic dressing and rest in bed, for more than three years, but without success. Treatment by oxygen was commenced six weeks ago, and the ulcer was rapidly healing, although the patient was the subject of Bright's disease. 2. A case of thirteen Ulcers of the Leg which commenced four years ago after an attack of typhoid fever. They had varied in size from a sixpenny piece to 2½ in. by 1½ in. in diameter. After three months' treatment by oxygen they had completely healed. 3. An epileptic patient, a girl aged eighteen, who had incurred a severe burn all across the upper part of the back nine

Digitized by Google

months ago. After the first few weeks the healing had come to a complete standstill, in spite of six months' treatment in a London hospital. Nine weeks ago the ulcerated surface measured 11 in. by 9 in. During this time it had been kept continually bathed in a mixture of equal proportions of oxygen and purified atmosphere by the knapsack apparatus, and it now measured 5½ in. by 3 in. Two cases of Alopecia, one very successful, and the other doubtfully so, were shown and are mentioned in our report of the Dermatological Section.

FRIDAY, AUG. 2ND.

The Anastomosis Button.

Dr. MURPHY (Chicago) gave a demonstration on the dead body of the method of using the button devised by him. He commenced by saying that seven points required attention in attempting to obtain union between two pieces of bowel. They are: (1) coaptation of surfaces, and the union should be between similar tissue—that is, the muscular coat should join the muscular coat, and the mucous membrane of one portion should be in contact with the mucous membrane of the other; (2) adhesions should form immediately; (3) sufficient calibre should be left at the point of union; (4) permanent organised adhesions should result; (5) the line of union must not contract to any great extent; (6) the process should be aseptic; and (7) the method employed should take the least possible time. He further pointed out that two sets of arteries supply the bowel—firstly the branches of the mesenteric arteries; and secondly, the "parallel artery," which runs along the mesenteric border of the bowel. Of these two sets the parallel artery is the more important for the life of the bowel, for the mesenteric branches may be tied for a length of bowel equal to seven inches without any sloughing resulting, while the parallel vessel cannot be tied for more than half an inch without causing sloughing. Hence it is necessary in dividing the bowel to remove less of the mesenteric border than of the convex side. In taking the running stitch round the bowel it is important to make an overstitch at the mesenteric border in order to secure the parallel artery. The method was demonstrated both for end-to-end anastomosis and for lateral anastomosis. The application of the method to resection of the rectum was also shown.

The Results of Operative Treatment of Injury or Disease of the Cervical Vertebræ.

Mr. VICTOR HORSLEY read a paper on this subject. The cases on which the paper was based were seven in number, and in each laminectomy had been done for caries or for fracture. All the patients recovered. Case No. 1 was admitted to hospital in 1888 with caries of the atlas and axis. There was complete paralysis of all four limbs, and the skin was dusky from interference with respiration. The arches of the atlas and axis were removed. Power began to return on the sixth day. The patient is now well except for some wasting of the interossei. Case No. 2.—There was caries of the fifth and sixth cervical vertebræ, weakness of the intercostal muscles and of the lower limbs. There was no sensory paralysis. Laminectomy of the affected vertebræ was performed, and the patient recovered. Case No. 3.—There was caries of the lower cervical vertebræ, with complete paralysis in the legs and right arm, and a little power in the left arm. The vesico-rectal centre was interfered with. Laminectomy of the third to seventh cervical vertebræ was performed. On the third day some return of power was noticed, but this was only ephemeral, and very little further progress was made. Three months afterwards the patient left the hospital, and a month later died. Case No. 4.—There was fracture of the cervical spine, with paralysis of all four limbs, which had lasted eight months. The paralysis began to extend. Analgesia was present, and this always points to an affection of the central grey matter of the cord. The laminæ of the fifth and sixth cervical vertebræ were removed, and the thick fibrous tissue was dissected off the dura mater. The patient steadily improved, and only wasting of the interossei remained. Case No. 5.—The patient had fallen from a cart, striking his head and right shoulder. He walked about for a week, but gradually lost power in all his limbs. When admitted to Queen's-square Hospital fracture of the sixth cervical vertebra was diagnosed. The left optic disc was swollen. Laminectomy of the fourth, fifth, and sixth cervical vertebræ removed a ridge which had been pressing on the spinal cord. Power began to appear on the twelfth day. He has since recovered completely. Case No. 6.—The patient sustained a fracture of the sixth cervical vertebra; the onset of paralysis was gradual. There was marked contracture and well-marked anæsthesia of the post-axial border of the upper limbs. The arches of the sixth and seventh cervical vertebræ were removed when a projecting ridge was felt, but on extension this disappeared. He is recovering slowly. Case No. 7.—The patient had struck the fore part of his head and after walking 200 yards rapidly became completely paralysed. After partial recovery spastic paraplegia appeared, with post-axial anæsthesia of the upper limbs. The laminæ of the sixth and seventh cervical vertebræ were removed. Permanent recovery commenced three weeks after the operation. He can now walk a mile. In many of these cases there was an ephemeral recovery followed by a return of the paralysis, this probably being due to œdema arising in the cord.

Sir W. MACCORMAC wished to know how one could distinguish between cases suitable for operation and those which would recover without operation.

Sir WM. STOKES (Dublin) asked why removal of the laminæ should relieve caries which affected the bodies of the vertebræ.

Mr. NOBLE SMITH asked at what stage of caries should an operation be performed. He remarked that a large number of cases recovered from paralysis in caries of the spine without any treatment. Mr. C. B. Keetley had operated in one case of fracture of the spine, but the patient died, and the cord was found to be completely divided. In a case of caries in which he had operated with a satisfactory result he was not inclined to attribute the result to the operation. He thought extension was of great value.

Mr. DAMER HARRISSON (Liverpool) also thought that extension was of great value.

Mr. FREER (Birmingham) considered it very difficult to decide when to operate.

Mr. MAYO ROBSON said he had operated in one case for fracture. The patient had previously been operated on by him for caries. Recovery was very partial. He thought that operative interference was very seldom needed.

Mr. HORSLEY, in reply, said that complete vaso-motor paralysis and entire loss of deep reflexes showed complete division of the cord. In an ordinary case extension should be tried for six or eight weeks. Laminectomy relieved caries because there was always a thickening over the dura mater, which was a source of pressure. In some cases the reason for operating was impending asphyxia.

Mr. C. A. MORTON (Clifton) showed a specimen in which lateral intestinal anastomosis had been performed three months before death. The cause of the operation was malignant disease of the cæcum.

Mr. MAYO ROBSON (Leeds) read a paper on a series of cases of Colectomy. In four of them he had employed the bone bobbin and in one Murphy's button. Two of the cases were operated on for malignant disease of the bowel and three for fibrous stricture. He preferred the bone bobbin to the button, and with it he used the continuous suture.

Mr. GREIG SMITH was of opinion that when a typhlotomy was performed for acute intestinal obstruction the colectomy should be made a part of the first operation by bringing the growth outside the abdomen and passing skewers underneath it. A few days later the growth could be removed without an anæsthetic.

Dr. KEEN, Mr. G. HAMILTON (Liverpool), and Mr. H. ALLINGHAM having spoken,

Mr. HARRISON CRIPPS said he preferred not to do too much at once; of four cases recently of resection of the bowel in which Murphy's button was used all died.

Professor MACEWEN (Glasgow) said he had never tried anything but stitches, and at present he still preferred to use stitches.

Mr. MAYO ROBSON, in reply, said that in acute intestinal obstruction immediate relief was the chief thing.

Complications occurring in Inguinal Colotomy.

Mr. HARRISON CRIPPS read a paper on this subject. There was often some difficulty in finding the bowel; the best method was to pass a finger along the brim of the pelvis, and, if necessary, have some water injected into the bowel at the same time. Occasionally it happened that there was no sigmoid meso-colon; in this case the bowel could not be brought up to the abdominal wall; the operator could close the wound and open the cæcum or the ascending colon; or he might stitch the

Digitized by Google

parietal peritoneum to the bowel wall, or turn up peritoneal flaps from the bowel and attach them to the parietes. Prolapse is nowadays rare, as more bowel is drawn out. The incision should be high up—as high as the level of the umbilicus. If undue contraction occurs, a spring dilator is the best instrument to use.

Mr. W. ANDERSON read a paper on three cases of Sacless Herniæ of the Sigmoid Flexure through the Left Inguinal Canal, with an anatomical specimen. Two of the cases were oblique and one direct. The bowel was covered on the concave side by peritoneum. Attempts at radical cure were not very successful.

Mr. L. BIDWELL said that he had had a similar case in which strangulation had occurred. He attempted to form a mesentery for the sigmoid flexure, but the bowel sloughed and a fæcal fistula formed.

Mr. W. D. SPANTON read a paper on three cases of Splenectomy. One of the cases recovered. In the two fatal cases a large amount of blood was found in the abdominal cavity. He had drawn up a table of all recorded cases of the operation, and among the conclusions arrived at were these: (1) that it is never justifiable for leucocythæmia, as there is a mortality of 96 per cent.; and (2) that the mortality has been steadily diminishing, for from 1865 to 1875 the mortality was 80 per cent., during the next decade it was 51 per cent., and during the last ten years it had fallen to 19 per cent.

Mr. C. CATHCART (Edinburgh) demonstrated a simple form of Exhaust Pump for use after supra-pubic cystotomy.

PSYCHOLOGY.

FRIDAY, AUG. 2ND.

Epilepsy and its Relation to Insanity.

Dr. GOWERS in opening this discussion pointed out that the knowledge needed for the discernment of the relation between the two diseases can only be obtained from the side of insanity, although what information it is that is wanted can be only clearly perceived from the side of epilepsy. To supply it, however, associated effort is necessary. Restricting the question to insanity and idiopathic epilepsy, both maladies must be regarded as affections of the cortex of the brain, although we have no knowledge of the changes which underlie them; but if the recent progress in histology and physiology can be trusted we have not yet looked in the right place. Attention has been fixed on the nerve cells, but it is in the spongy grey matter between the cells that the affections must arise. Here we have not yet reached the recognition of normal structure, much less of pathological change. Hence our present study can be only clinical. The hereditary relationship between the two diseases has yet to be worked out from the side of insanity, and this is one of the questions most urgently needing combined effort. The frequency with which insanity can be traced in the families of the epileptic is approximately known; all facts, however, regarding inheritance are below the truth. It is interesting to note that in the series of 1450 cases analysed for the first edition of "Epilepsy" inheritance was traceable in 35 per cent., but in another series of almost the same number, recently analysed for a forthcoming edition, the percentage rises to 44·5 per cent. This is because a larger proportion of the cases were seen in private, and in them the facts of heredity can be far more certainly obtained. When these private cases are separately considered the proportion of heredity rises to 48·4 per cent., so that at least one-half the cases of epilepsy are inherited. This shows the importance of discriminating the source of information in the facts regarding insanity in each series; the inherited cases, considered separately, furnish, as would be expected, the same proportion of cases of insanity in the family. It was met with in one-third. Epilepsy existed alone in two-thirds. No information can be given regarding the character of the epilepsy in cases with insane heredity, but far more important is the information which should be forthcoming from asylums regarding the cases of insanity in which there is a family history of epilepsy. Post-epileptic mania was then considered as replacing in men the post-epileptic hysteroid convulsion of women and young males, and the question discussed whether such mental disturbance does not sometimes replace an attack. This is suggested by the peculiar and elaborate mental warnings which sometimes occur, and which show how complex may be the initial process of the fit. Another important relation is the occurrence of an attack of insanity in the course of epilepsy. Here, again, we are quite without definite information, and it can only come from asylums. It seems probable that such transient insanity is most common in patients with a complex mental aura, but the facts cannot be discerned from the side of insanity, because the attack withdraws the patients from observation and they are generally not seen again. Indeed, the chief object to be obtained by the discussion was to awaken attention to the need for a joint attempt to ascertain facts. Such an attempt could only be made by the appointment of a committee to receive information and to obtain it by definitely indicating the facts that are needed. The questions involved are of great importance both socially and medically, and warrant a deliberate effort to secure the knowledge which no one person can obtain, and which, moreover, can only be obtained in the main from the alienistic side, but only in its completeness, by the coöperation of those under whose notice each class of diseases comes.

Dr. FLETCHER BEACH expressed his concurrence in Dr. Gower's views, especially concerning the difference in the statistical data from different social classes and referred to the difficulty experienced in eliciting facts concerning heredity in the lower classes. He did not think that heredity, by itself, was sufficient to produce epilepsy or insanity. He was of opinion that this result was due to the coöperation of many factors. He thought much good could be achieved by a more frequent conference between alienists and general physicians. Much valuable information could, and he hoped would, be obtained by devising some mode of coöperation.

Dr. HYSLOP thought we were in danger of making our notion of epilepsy too wide and too vague, so as to include every condition in which there is a sudden or explosive physical or psychical action. He wished to ask what is really meant by the term "epilepsy," and observed that there is a great difference between epilepsy and what are called "epileptiform attacks." At present the former term was used much too loosely. He also remarked on the difficulty he had in understanding Dr. Hughlings Jackson's views of the nature of epilepsy, and confessed that he could hardly grasp their signification.

Dr. MERCIER referred to the epileptics in asylums, many of them cases of a class comparatively rare outside asylums—cases of *petit mal*, cases in which the fits are preceded by elaborate auræ or followed by elaborate automatic actions. The great importance of the subject was shown by the fact that 1300 epileptics were annually admitted into the asylums of England and Wales. He suggested that Dr. Gowers might assist the asylum physicians by indicating the lines upon which such an investigation as he suggested might be carried out

Professor BENEDIKT (Vienna) referred to a class of cases which are in reality epileptic, but which are not recognised as such. Their manifestation consists of a psychosis, such as a fit of passion. They are very rare, and only occur under special circumstances. He then made a few remarks about epileptics who are the subjects of sexual perversions.

Mr. CONOLLY NORMAN said that he had seen several cases of epileptic mania in women, and was surprised that Dr. Gowers had not. Excellent descriptions of the mental states in epilepsy abound in memoirs in the psychiatric journals, as the papers of Sanders in Germany and Howden in this country. He also referred to the difficulty of obtaining the histories of patients admitted to the large asylums in this country, the patients themselves being of course frequently unable to give any account of themselves.

Dr. HUGHES (St. Louis) referred to the interest and importance of this subject, and was of opinion that observation had proved the unvarying kinship between all epileptoid states. He cordially eulogised the researches of Dr. Hughlings Jackson as to their effect in elucidating the various phenomena of epilepsy, especially those occurring in the obscure forms of *petit mal*.

Dr. JAMES TAYLOR referred to the influence of drugs on epilepsy and the possible relation of variations in the mental condition to the drug administered and the dose of the drug.

Dr. NICOLSON (Broadmoor) also spoke.

Papers.

Dr. BONVILLE FOX next read a paper on a Medico-legal

Digitized by Google

Case, illustrating the anomalies and absurdities of the law as at present administered, more especially in regard to the application of the "knowledge of right and wrong" test.

Dr. WEATHERLY, Dr. MERCIER, and others spoke.

On Morbid Doubt.

Dr. HARRY CAMPBELL read a paper on Morbid Doubt. He related several cases of such doubt arising in the mind—e.g., as to whether a certain act, such as posting a letter, had been done or not. In its extreme degree such morbid doubt became almost, if not actually, insanity.

Dr. WEATHERLY thought this was merely an exaggeration of the ordinary feeling of doubt as to whether a certain act had been done or not.

Dr. HUGHES (St. Louis) regarded its persistence as the characteristic of morbid doubt, and was not inclined to regard the instances of Dr. Weatherly as true examples of morbid doubt.

Dr. CLIFFORD ALLBUTT had seen numerous cases of the slighter forms referred to, and he was not inclined to attach much significance to them. He certainly knew instances of patients who for years had been troubled with the doubt referred to by some of the speakers—e.g., as to having locked a door &c.—and this he felt sure did not necessarily indicate even a danger of insanity.

Fractured Ribs in the Insane.

Dr. A. W. CAMPBELL read a paper on a Comparison between the Breaking Strain of the Ribs of the Sane and the Insane. He finds as a result of experiment that the breaking strain of ribs in the insane is but very slightly different from that in the sane. On the other hand, the average breaking strain of the ribs of those dying from chronic and wasting disease is lower by about 6 lb. than that of patients succumbing to some chronic but not wasting affection; while the average breaking strain in the latter case is less than that in patients dying from acute disease or accident. In general paralysis, however, the breaking strain is about 20 lb. below the normal standard. In both sane and insane there are cases in which the ribs possess an exceedingly low breaking strain. In such there are either architectural defects or the density and elasticity are diminished as a result, probably, of chemical changes due to defective assimilation.

Dr. C. H. BOND next read a paper on the Relation of Diabetes to Insanity. He remarked on the interest of this question to the general physician, the neurologist, and the alienist. It has been denied that glycosuria is of frequent occurrence in the insane. This is true if all cases are included; if only recent ones are, it is probably not. In 175 cases the urine was examined soon after admission and frequently afterwards. In twelve instances sugar was found, and of the twelve, six were melancholics; indeed, mental depression existed in all. An insane heredity was present in more than half the cases. Four chronic female cases are also described in whom diabetes developed during their residence at Banstead. Three of them died and a full account of the necropsies was given. In all the cases a marked history of previous alcoholic excess was notable. The question of the inter-relation of psoriasis, insanity, and diabetes was also alluded to.

Voluntary Boarders in Asylums.

Dr. PERCY SMITH read a paper on this subject. Admitting patients as voluntary boarders in asylums had grown largely of late. The most important restriction is that the consent of the Commissioners in Lunacy must be obtained in the case of a private asylum. The following were instanced as suitable cases for such provision: (1) recurrent cases; (2) cases of mild melancholia; (3) patients with homicidal feelings, distrustful of their own self-control; (4) cases with maniacal excitement after epilepsy; (5) early cases of general paralysis; (6) some cases of partial weak-mindedness; (7) cases of drug habit or alcoholism; (8) patients with hallucinations; (9) patients wishing to remain for convalescence; and (10) certain classes of patients, especially medical men or nurses. Patients may simulate the milder varieties of insanity to enjoy the comfort of an asylum. To obviate this, great care is necessary with histories. There is at present no arrangement for admission of voluntary boarders of the poorer classes to county asylums, and it is worth consideration whether some provision of this nature is not desirable. Dr. Percy Smith also gave an account of his own procedure in regard to applications for admission as voluntary boarders.

The Law in Relation to Single Patients.

Dr. L. A. WEATHERLY read a paper on this subject, in which he pointed out the curious discrepancies that exist between the law and the practice, especially as to the presence of two or more patients in a private house and the inadequate provision for supervision of their treatment. He suggested that the best way to provide for such cases was—(1) to educate the public to recognise that insanity is no crime, but a disease; (2) that in cases in which certification would be difficult it should be insisted upon that a report be sent to the authorities stating that A B has been placed in a certain house for care and treatment, but that the unsoundness found is not sufficient to admit of certificates being signed; and (3) that to admit a proper supervision of all these cases, district officials should be appointed to act, as it were, as subcommissioners. Such a system would then form a most useful adjunct to the system of asylums.

Dr. HAYES NEWINGTON and Dr. DOUGLAS also spoke as to the imperfections and anomalies of the present system.

The work of the Section was brought to a close with a cordial vote of thanks to the President, proposed by Dr. HAYES NEWINGTON and carried by acclamation.

PHARMACOLOGY AND THERAPEUTICS.

FRIDAY, AUG. 2ND.

The meeting was presided over by Dr. MITCHELL BRUCE, and subsequently by Dr. MCHUGH. The first part of the proceedings was occupied by papers on the therapeutic value of the waters of various spas.

Dr. FORTESCUE FOX (Strathpeffer) read a paper on the Therapeutic Uses of the Waters of Strathpeffer Spa. The waters were most useful in the treatment of conditions occurring during middle life. Caution was necessary in the use of the sulphur waters, which, if long continued, might produce anæmia. The waters were contra-indicated in all acute febrile states, in acute congestion or inflammation of the viscera, in acute rheumatism and tuberculosis, uncompensated heart disease, and albuminuria. The use of the waters seemed to be the remedial factor in spa treatment, change of air, scene, diet, and surroundings being insufficient to account for the great benefit received in so many cases of chronic disease.

Dr. S. HYDE (Buxton) read a paper on the Therapeutic Value of the Waters of Buxton. After referring to the variety of waters occurring at and around Buxton—saline, sulphur, and ferruginous—the cases suitable for the treatment were discussed. Subacute rheumatism was especially likely to be benefited. Although at first the treatment usually brings about a return of the acute symptoms, these are of short duration, and rapid progress towards recovery quickly follows, a large number of patients being completely cured. In acute gout the internal use of the waters is alone indicated, but in chronic gout the use of baths in addition is most useful. In rheumatoid arthritis the combined internal and external treatment together with massage gives satisfactory results. Massage is a valuable adjunct in many conditions, but electricity is not particularly beneficial. The treatment yields good results in many other conditions—lumbago, peripheral neuritis, and certain skin affections, particularly those dependent upon gout. The remarkable effects produced by the *natural* mineral springs was next commented upon, and it was pointed out that however closely an artificial water, prepared synthetically, resembled a natural one, the former was lacking in some peculiarly subtle properties which gave the "character" to the natural water and rendered this much more efficient in therapeutic value. The conditions of change of life and surroundings accompanying treatment at a spa were not sufficient to explain the benefits received.

Dr. A. S. MYRTLE (Harrogate) alluded at the commencement of his paper on the Therapeutic Value of the Waters of Harrogate to the fact that there was some property in natural springs which was lacking in artificial waters, however closely they resembled the natural. He considered that strict dieting was unnecessary while undergoing the treatment; patients might have anything in reason, food and drink, provided it did not disagree and was taken in moderation. He was in the habit of recommending for breakfast "any-

Digitized by Google

thing you like, but not too much of it"; for lunch, ditto; and for dinner, ditto. The sulphur waters were the only ones used externally, the sulphuretted hydrogen contained in them being sedative in nervous conditions and in affections of the gastric and bronchial mucous membranes. The other waters were stimulant, diuretic, and tonic. In chronic cardiac diseases the waters were most useful if used with care.

Mr. W. TOMLINS (Droitwich) read a paper on the Brine Baths of Droitwich. After referring to the large amount of saline constituents which these waters contain and quoting analytical figures, the cases suitable for the treatment were discussed. In conclusion, attention was drawn to the attractiveness of the scenery and to the favourable climatic conditions of Droitwich.

Dr. PARSONS referred to the value of spa treatment in diabetes and other diseases.

Dr. CUFFE and others also took part in the discussion.

Dr. HERBERT SNOW read a paper on "Loretin," an organic iodine compound discovered by Claus of Freiburg, and possessed of antiseptic properties. Loretin is a yellow crystalline powder, but slightly soluble in water, and forming emulsions with ether, oil, and collodion. It forms neutral salts with alkalies, which are freely soluble in water. Loretin is odourless and non-poisonous, and greatly superior to iodoform in germicidal power. It is also a most efficient deodorant, almost instantly annulling the fœtor of sloughing cancerous sores. Dusted into deep wounds, it completely precludes subsequent suppuration, and no bad symptoms had been observed after its use. Applied to the skin or to a granulating sore it is perfectly unirritating.

Dr. F. R. WALTERS read a paper on the Subcutaneous Use of Guaiacol. When injected under the skin guaiacol was found to be very irritating and producing sloughing. Injected into the muscular tissue the irritating properties were less marked, and considerable doses could be administered without constitutional disturbance.

Dr. DE BACKER (Paris) read a paper on the Treatment of Tuberculosis by Living Ferments. Yeast species are made use of and are injected in the living state subcutaneously. They are said to act therapeutically by a sort of phagocytic action.

LARYNGOLOGY AND RHINOLOGY.

WEDNESDAY, JULY 31ST.

The Etiology of Mucous Polypi of the Nose.

Professor GAYE (Amsterdam) opened a discussion on this subject. He had been unable, he said, to demonstrate any causation in the majority of his cases of nasal polypi, but he had in other cases seen and proved them to be originated by fetid ozæna, rhinoliths, and empyemata of the accessory cavities, but he thought chronic catarrh, irregular septum, and habitual mouth-breathing might have a bearing on the etiology of the complaint. He finally alluded to the possibility of climatic influences, giving as an example a place in Holland where nasal polypi were said by the inhabitants to be unusually prevalent.

Dr. LUC (Paris) maintained that the causation of nasal polypi by empyemata of the antrum and other accessory cavities was far from being a frequent one. His chief criticism of Woakes' views was the entire absence of clinical proof by that authority. He considered von Zeim's work to have been very beneficial to nasal surgery. Myxomatous degeneration was the form of middle meatal response to constant irritation, and drew attention to folds of the mucosa as being an etiological factor in nasal polypi. Chronic catarrh and bone lesions were occasional causes, but many of the growths were of spontaneous origin.

A paper by Professor ZUCKERKANDL of Vienna was read on this subject. He said the majority of writers agree that the polypi and polypoid hypertrophies of the nose were not really neoplasms, but inflammatory hypertrophies due to a chronic local inflammation. He gave as proofs of this: (1) the constant presence of round-celled infiltration in the growths; (2) the presence of other inflammatory changes at the base; (3) that polypoid hypertrophies develop into polypi; (4) polypi can be caused by the presence of a rhinolith; (5) there is no sharp line between polypi and normal tissue; (6) their tendency to recur; and (7) the absence of congenital polypi. Polypoid hypertrophies of the lower turbinated bones might be called polypi, as they have equally with those of the middle meatus the same characteristics and the same causation. He severely criticised Woakes' theory of ethmoiditis, remarking that syphilis and allied conditions were the probable originators of the necrotic conditions; he had examined all available bases of polypi and polypoid hypertrophies, and never found them necrotic, but, on the contrary, especially at the edges of the ostium maxillare, a new bony outgrowth was apt to arise.

Dr. P. MCBRIDE commenced his paper by a graphic description of nasal polypi. He said most observers considered nasal polypi to be simply œdematous fibromata; he alluded to the so-called papilloma of the inferior turbinated bones which he described as similar to polypi of the upper tracts. As to the etiology he put forward the view that a small vascular loop of inflammatory products caused a projection of the mucous membrane, which hung down, and which became polypoid from the action of gravity. This would, however, only account for a part of the growths. Empyema of the antrum accounted for many of the growths; and it was by no means improbable that a faulty histological condition was sometimes present which predisposed the individual to the disease. He thought Woakes' theory was not substantiated, nor did he quite agree with Grünwald; his statement was too broad. In his own tables he found males to be the most frequent sufferers, and the ages of twenty to thirty to be the most usual time of life to find these growths

Dr. HODGKINSON was not able to add much that was new. Empyema of the accessory sinuses was not uncommon in connexion with these growths; caries of the ethmoid could not be considered as a usual accompaniment of polypi. We were, therefore, rather left to a predisposition theory.

Professor SCHMIDT (Frankfort) was inclined to attribute polypi entirely to inflammation of the mucosa and subjacent tissues by reason of some form of irritation.

Dr. SCANES SPICER quite agreed that hypertrophies of the middle and lower turbinated bone were of the same variety of tissue &c. He was not inclined to refuse Woakes' theory altogether, and he thought a great deal of the views expressed were from a faulty reading or interpretation of that author. The term "ethmoiditis" was an inclusive term including all the other tissues as well as bone, and in this disease necrosis was rare. He thought that whilst empyema of the antrum sometimes caused polypi sometimes the reverse was the order of things.

Dr. WM. HILL said the causation of these growths must be sought in irritation and inflammation of the mucous membrane. More than 50 per cent. of his own cases had been unassociated with either bone or antral disease. He drew attention to the similarity between nasal and aural polypi in regard to their being always connected with bone lesion in the nose and also that they were both lying bathed in moisture. He classified these growths into two varieties clinically: those cases in which pus was present and those in which it was absent, the latter being the more easily curable cases.

Dr. BOSWORTH (New York) had founded, on his own experience, the theory that the origin of nasal polypi was due to mucoid degeneration of the mucosa, primarily in the ethmoid cells, and as it increased in amount it was, as it were, squeezed out in the polypoid form as honey was when pressed out of the comb. The starting point of polypi is some inflammatory process.

Dr. DALY (Pittsburg) said he was quite convinced that very frequently there was dead or diseased bone underlying the seat of origin of nasal polypi, especially if they had existed for some years. The sensation imparted to the probe was quite different from that of healthy bone. He then directed the attention of the members to the great resemblance between temporary œdema with hyperplasia, as in acute catarrh, and the mucous polypi at present under discussion, and expressed his adhesion to the view that polypi arose from chronic inflammatory states. He had never seen antral disease as a precursor of polypi, but he had in several instances seen them produced by malignant neoplasms of the antrum.

Dr. JOHN NOLAN MACKENZIE (Baltimore, U.S.A.) argued in favour of the inflammatory origin of nasal polypi, not only because of its great probability, but also on account of its numerous familiar examples throughout the body. Rarefactive osteitis and caries might, and did, exist in certain cases, but that did not prove Woakes to be correct when he said "necrosis."

Mr. R. LAKE in his own researches had never found polypi &c. save œdematous hypertrophies of the mucous

Digitized by Google

membrane. He thoroughly disagreed with Dr. Hill's view of the similarity of the aural and nasal polypi. The former started as granulation tissue, developing into soft, then hard fibrous tissue, and later degenerating into myxomata, an entirely different life history to the latter.

Dr. NEWMAN (Glasgow) referred to the chemistry of the growths. It was not a mucoid infiltration, but merely œdema, water salts, and serum albumen. He also urged the importance of œdema in the production of the growths.

Dr. WATSON WILLIAMS drew attention to the very great rarity of myxomata in the nose; so rare was the condition that it might be excluded from the present discussion. He alluded to the work of Zuckerkandl, who had found in some the periosteum inflamed and in others new bone formation beneath the origin of polypi; he had himself observed the same sort of thing with much new bone formation. He was inclined to look on Hoffmann as affording useful help by his vascular theory.

Dr. DE ROALDES (New Orleans) also spoke, showing the almost universal absence of polypi in the negro to be due to his roomy nose.

Dr. GAYE, Dr. LUC, and Dr. MCBRIDE replied.

The Representation of Abduction of the Vocal Cords in the Cerebral Cortex.

Dr. J. S. RISIEN RUSSELL read a paper upon this subject. He reviewed briefly the valuable scientific work done by Semon and Horsley, who had discovered many points of great value, but who had been unable to find the cortical abductor centres in dogs and monkeys, though they had done so in cats. But they had demonstrated the existence of a focus in the internal capsule, the most natural deduction from which was that there did exist a connexion between this and certain areas in the grey matter which would cause abduction when stimulated. The predominant energy of the adductors was nullified by the following means. The adductor fibres were divided from the abductor fibres in the recurrent laryngeal nerve and the former divided. A stimulus applied now to a point in front of Krause's adductor centre caused abduction of the cords, whilst stimulation of Krause's centre on the side with the intact nerve resulted in adduction of that cord. In some dogs it was even possible to obtain the movement of abduction without this nerve division, and then the centre was found to be in the anterior composite gyrus below the adductor centre, only separated from the other by the supra-orbital sulcus. The focus in the cat corresponds with the first one discovered in the dog, but there the cat differs from the dog—cats always react. Two other centres were alluded to, that of Semon and Horsley in the cat, to which Dr. Risien Russell supplied an analogue in the dog, and one in the anterior composite sulcus, stimulation of which arrested the vocal cords in adduction.

The PRESIDENT congratulated Dr. Risien Russell on his paper, saying that he had succeeded in doing what he (the President) and Professor Horsley had failed to prove, and he should like to hear what Dr. Risien Russell's opinion was as to the unilaterality of the cortex regarding laryngeal movements.

Dr. BRYSON DELAVAN and Dr. WATSON WILLIAMS took part in the discussion, each quoting a case bearing on the points raised.

Dr. RISIEN RUSSELL replied that he had found no unilaterality in the cortical centres for the larynx.

The Vibration of the Vocal Cords.

Dr. A. HODGKINSON read a paper with the above title, in which he described a very ingenious method which he had employed for the last five or six years to demonstrate the parts of the cords which vibrated. He had adopted the sand picture plan, but instead of sand used finely powdered indigo to blow upon the cords, and by means of various pitches had been able to produce various pictures which were fairly constant, and which tended to show the cords had a greater amplitude of vibration at the central free edge, and the lower the pitch the longer the vibrating portion.

Dr. ILLINGWORTH read a paper on the Anatomy and Physiology of the Larynx.

THURSDAY, AUG. 1ST.

On the Infectious Nature of Lacunar Tonsillitis.

This subject was introduced by Professor B. FRAENKEL, who gave first a description of the usual course and symptoms of a case of ordinary acute follicular tonsillitis, showing how it simulated an infectious fever by its onset, course, and crisis, and by its splenic enlargement. He recommended excision of hypertrophied tonsils in a state of acute exacerbation; in these the pathological anatomy of the part could be studied, and such patients do not suffer at all more than usual. Microscopic examination of those tonsils showed an increase of emigration of the leucocytes from the follicles; these passed into the lacunæ. He referred to the occurrence of tonsillitis after intra-nasal operations, and he had found the same micro-organisms in both this and the usual form of tonsillitis. Micro-organisms are found even in the substance of the follicles. He had observed undoubted cases of transmission of the disease from one patient to another, and a chill—so frequent a cause—serves only to open the door, as it were, to these microbes.

Dr. MACINTYRE (Glasgow) referred to the confusion which existed from a bacteriological point of view in the classification of tonsillitis. He then considered critically the micro-organisms found in the tonsil before, during, and subsequently to an attack of tonsillar inflammation, referring incidentally to the non-pathogenic organisms of the mouth. He next considered the toxic effects of the micro-organisms and related cases much resembling typhoid fever in which the Peyer's patches became involved, one case ending fatally, and he referred to other lesions such as synovitis.

Dr. SEMON referred to the great importance of the subject.

Mr. LENNOX BROWNE said that the galvano-cautery when used in the nose was more frequently followed by tonsillitis than other intra-nasal operations; this was because the nose ceased to act as a filter. He considered rheumatism when associated with tonsillitis to be a case of auto-infection. He had found various organisms in this disease, but no specific one. Sanitation, or rather want of it, had much to answer for.

Dr. MORITZ SCHMIDT considered careful antisepsis of the nasal cavities and plugging with antiseptic gauze diminished the risk of traumatic lacunar tonsillitis supervening.

Dr. ST. CLAIR THOMSON said he considered traumatic lacunar tonsillitis to be due to plugging of the nose by the swollen mucosa.

Dr. GLEITSMANN had feared to excise tonsils which were inflamed, dreading the large open wound in the state of the surrounding parts. He used trichloracetic acid after the cautery, and so kept the nostrils patent, but that did not stop the trouble.

Mr. L. LAWRENCE referred to the connexion between tonsillitis and rheumatic fever.

Professor FRAENKEL and Dr. MACINTYRE replied.

The Functions of the Laryngeal Ventricles and Ventricular Bands.

Dr. A. HODGKINSON read an interesting paper on this subject, in which he arrived at the following conclusions—that the dust particles were prevented from acting as mechanical irritants on the cords by the action of mucus and mucus-cells, and that, as by his observations he had concluded that mucus &c. from the larynx passed over its posterior wall, so the seat of election of tuberculous infection was due to this likewise. He also said he had himself seen blood flowing out from the ventricles, and thought that we must not conclude that all coughed-up blood &c. necessarily came from the lung, and that the cords were cleared by deglutition.

Dr. CATHCART and Dr. MORITZ SCHMIDT combated his views, urging the theory of Wylie as the correct one.

Intra-Laryngeal Injections.

Dr. BRONNER (Manchester) read a paper on some Cases of the Larynx and Bronchi treated by Intra-laryngeal Injections, in which he referred to the absorption by the bronchi of various fluids. Menthol solution (5 to 20 per cent.) is useful to allay cough and to deodorise; terebene is very efficient for profuse and offensive sputum—10 to 50 per cent. with menthol solution, or 2 per cent. ol. pimentæ, or 3 per cent. europhen; and soda or iodine in deficient secretion. Cocainisation is to be first done. With a little practice Dr. Bronner says the operator can more or less direct the stream into the bronchus selected. The first case quoted was that of a man who suffered from a tickling in the throat at night which prevented sleep; he was quite cured by this method. The next case was very similar, and was cured. The third

Digitized by Google

was a case of atrophic laryngitis; this was nearly cured, and the distressing cough is almost gone. Other cases were bronchitis (chronic) and chronic bronchitis and asthma, both practically cured. In a case of laryngeal phthisis the distressing cough was stopped.

FRIDAY, AUG. 2ND.

The Indications for Early Radical Operation in Malignant Disease of the Larynx.

Dr. BRYSON DELAVAN (New York) and Mr. BUTLIN opened this discussion, the former taking up the more conservative position. The PRESIDENT, Dr. SEMON, Dr. J. N. MACKENZIE (Baltimore), Professor MORITZ SCHMIDT (Frankfort-on-Maine), Dr. SCANES SPICER, Dr. R. WOODS (Dublin), Dr. Lawrence, Dr. DUNDAS GRANT, Dr. HODGKINSON, and others took part in the discussion, Dr. DELAVAN and Mr. BUTLIN replying.

Thyrotomy.

Mr. P. DE SANTI read a paper on the Operation of Thyrotomy, with a short account of the cases in which it has been performed at St. Bartholomew's Hospital during the last nine years. Thyrotomy was first performed at St. Bartholomew's Hospital in 1886; since then nine thyrotomies had been performed there for malignant disease and eight thyrotomies for innocent growths and other causes. Mr. Butlin's private cases were nine for malignant disease and two for innocent growths, which altogether make twenty-eight thyrotomies. Mr. de Santi preferred chloroform to ether in this operation on account of the excessive secretion of saliva. He also laid stress upon the sponge round the Hahn's tube being aseptic. He advocated the use of a 5 per cent. solution of cocaine to the larynx after division of the cartilage, to lessen the hæmorrhage and remove reflex excitability. The sponge cannula is to be removed, and the wound dusted with iodoform and covered with gauze; the patient should be kept on his side with the head low in order to facilitate the flowing away of the discharge and lessen the risk of pneumonia. The feeding of the patient during the first two days is chiefly done by nutrient enemata; on the day following the operation the power of swallowing should be tested.

Vocal Defects among School Board Teachers, with special reference to the occurrence of Teachers' Nodes.

Dr. WILLIAM MILLIGAN (Manchester), after enumerating the various catarrhal conditions and their more usual sequelæ, proceeded to node formation. He had seen nodes in girls aged fourteen. He dwelt upon the factors which played an important part in the development of catarrhal and subsequent changes, such as the size of the class, the age of the teacher, want of exercise, and the like.

On Chorditis Tuberosa.

Dr. A. HODGKINSON (Manchester) dwelt upon the pathological anatomy more than the clinical aspect, which was more fully developed by the preceding speaker. The mechanical cause here was the friction of inflamed parts of the cord, which takes place usually at that point; the nodes appear, and the pathological picture was clearly defined.

ERRATUM.—We find that in our report of the discussion upon Chronic Glaucoma we have attributed to Mr. Nettleship, who opened the debate, the remarks made by Mr. Power. Mr. Nettleship, in his introductory words, submitted "that it was undesirable to maintain the distinction between typical chronic glaucoma and atrophy with cupping of the optic disc; that the risks of iridectomy in producing rapid deterioration of vision were less than has been supposed; that retarded progress of the disease is often, and permanent arrest not rarely, secured by iridectomy performed early; that it is often right to operate in the premonitory stage of glaucoma; and that iridectomy is nearly always to be preferred to sclerotomy for chronic glaucoma."

THE MUSEUM.

(*Continued from p. 381.*)

II.—MEDICAL AND SURGICAL APPLIANCES.

SOME of the most important exhibits which may be grouped under this head were arranged in that section of the museum held in certain of the rooms of King's College. Thus the Society of Anæsthetists had an excellent collection of the various appliances employed in connexion with the administration of anæsthetics; and Messrs. Thos. J. Syer and Co. (Wilson-street, E.C.) explained their patent combined consulting-room couch and operating-table, with its improvement for head support and throat examination, while Messrs. Down Bros. (Thomas-street, S.E.) had a space completely equipped as an aseptic operating-theatre, and their aseptic furniture for hospital wards and out-patients' rooms, and a completely fitted aseptic surgeon's consulting- and operating-room, formed an interesting group instructive of the requirements of modern advances. A special feature of the exhibit of Messrs. Allen and Hanburys (Plough-court, Lombard-street, E.C.) was the operating-table, which formed part of the appliances of a well-appointed operating-theatre. It is made entirely of enamelled iron and is provided with a series of pipes for the circulation of hot water, so that the temperature of the patient may be maintained. The surface frame is movable and easily adjusted for the Trendelenburg and other positions. Various patterns of operating-cushions, securing cleanliness in operations, were also shown, as well as several designs of consulting-room couches, while the special aseptic washhand stand for the foot movement only, so that the operator does not touch the tap with his hands, must be numbered amongst the important novelties of this section.

As mentioned elsewhere, Messrs. Allen and Hanburys had a most imposing array of surgical instruments in the examination-hall—far too numerous to be even alluded to. We must be satisfied, therefore, with referring to some of them, which, regarded as "up-to-date" appliances, may be taken as examples of the rest. Several advantages, for instance, are claimed for a new rectal speculum, designed by Mr. E. C. Ryall, and a new midwifery forceps with detachable aluminium handles presents some obvious improvements, since it is aseptic and easily sterilised, and the light handles are easily detached by means of a spring catch. Then should be included the Murdoch-Cameron midwifery forceps, adapted for use in cases of marked contraction of the pelvis, even to as much as three inches; a modification of Dr. Champetier de Ribes' bag for induction of premature labour, obviating increased tension in the uterus and the danger of displacing the child's head; Mr. J. S. Ellis's modification of Sir Spencer Wells' and Mr. Lawson Tait's clamp for the compression of uterine fibroids; improved aseptic midwifery bags with movable linings; Mr. Ryall's double probes for fistula; the now well-known anastomosis buttons (Murphy); the Allenburys' chrismaline atomiser and powder insufflator; and, lastly, the hypodermic syringes with platino-iridium needles for the administration of antitoxic serum, which this firm supply direct from the British Institute of Preventive Medicine.

It is hardly necessary to state that the exhibit of Messrs. Arnold and Son (West Smithfield) consisted of all sorts of improvements, comprising hypodermic syringes, hæmorrhoidal clamps, vaginal douches, exploring and drainage tubes, catheters, aseptic instruments and case, urethral knife, uterine stem, binaural stethoscope, ice caps (for ophthalmic application), complete midwifery sets, amputation cases, and so on—all constructed in accordance with the suggestions of medical men. On account of their importance and interest doubtless no less than four entire pages of the catalogue were devoted to the list of appliances of Messrs. Down Bros. (Thomas-street, S.E.). Among their comparatively recent specialities should be mentioned Dr. Herschell's improved binaural stethoscope, provided with a lever by means of which the joint may be clamped and fixed at any point, thus obviating the use of a spring, which may press too severely or be too slack; a chest-piece, with finger-rest (suggested by Mr. G. A. Skinner), which is a useful and convenient adjunct to the binaural stethoscope; a new midwifery bag; and the anastomosis buttons of Dr. Murphy for lateral and end-to-end approximation.

Amongst the interesting appliances of Messrs. Burroughs, Wellcome, and Co. (Snow Hill-buildings, E.C.) their "insufflator" should be specially noticed. It is a very satisfactory instrument for the application of dry powders by insufflation to the nasal and oral mucous surfaces, sores, abscesses, and so on, and can be directed and worked with one hand. It is also provided with interchangeable powder cylinders, and may have attached to it a tongue depressor, a branched delivery tube, or a vaginal tube for special purposes. The

Digitized by Google

hypodermic and ophthalmic pocket cases of this firm, as also the patent aluminium syringe, are now so well known, and present advantages which are so manifest, as hardly to need mention. Every possible requisite employed in the treatment of disease by electricity was to be found in the striking exhibit of Mr. K. Schall (Wigmore-street) where, towering above the other appliances, was a large Wimshurst machine, which by the crack of its lightning-like sparks served as a powerful attraction in this section of the museum. There were batteries for faradaisation with acid and dry cells, batteries for galvanisation and electrolysis (continuous current), galvanometers, rheostats, electrodes, and batteries and instruments for galvano-cautery, for surgical lamps, for laryngoscopic, ophthalmoscopic, and other obvious exploratory purposes, &c. The "antrophors," exhibited by Messrs Thos. Christy and Co. (Lime-street, City, E.C.), for the treatment of urethral and prostatic diseases, consist of flexible spiral springs coated with an insoluble rubber covering to guard against irritation and to prevent decomposition of the medicament by the action of the metal spring. The soluble medicated mass covers the first insoluble coating and when inserted into the urethra gradually melts and is absorbed by the mucous membrane. Messrs. G. and G. Stern (Gray's-inn-road, W.C.) showed a novelty in the shape of breast protectors, which they call the "Neena breast shields." They are made of a light, firm, material, and afford an easy and comfortable support for the breast in health or disease. An important provision in these is also a series of small perforations by which ventilation is secured, while the material admits of cleansing, which with care need not affect the shape. Prominent amongst the surgical appliances, including antiseptic dressings, artificial limbs, aseptic instruments, and so on, of Messrs. Ferris and Co. (Bristol) was their "ever ready" caddy—a modern *sine quâ non* of the general practitioner—which is a neat and tidy storehouse for the textile materials, plasters, dressings, &c., used in surgical work. Mr. J. H. Montague (New Bond-street, W.), besides exhibiting many new and important surgical instruments and appliances, including Eric France's phimosis scissors, also showed some latest developments connected with electro-therapy. Ophthalmic instruments were well represented in the exhibit of Messrs. Curry and Paxton (Great Portland-street), who showed ophthalmoscopes, perimeters, optometers, trial glasses, glasses for astigmatism, &c., and various opto-electric appliances. Messrs. J. Hewlett and Son (Charlotte-street, E.C.), amongst their exhibits, submitted to inspection a bone forceps with serrated edge and closing screw for dividing metacarpals, phalanges, &c., made at the suggestion of Dr. T. H. Morton of Sheffield.

Antiseptic dressings, prepared according to the formulæ of Sir Joseph Lister, and including gauzes (carbolic, double cyanide, &c.), lints, wools, tows, ligatures, and sutures, formed the feature of the preparations of Messrs. Macfarlan and Co. (Moor-street, E.C.), although a specially purified chloroform for anæsthetic purposes, costing, it is stated, about half the price of chloroform made from rectified spirit, should also be mentioned. Similar preparations were shown by Messrs. Robinson and Son (Fann-street, Aldersgate-street, E.C.), whose speciality is absorbent cotton-wool placed between absorbent gauze (well known as Gamgee tissue)—the *ne plus ultra* dressing for wounds &c. The "Domen" belts, corsets, bandages, &c. of the Domen Belts Co. (Moor-lane, E.C.) are sufficiently well known to the profession on account of the excellence of their design to need no more than passing allusion. A glance at the excellent assortment of surgical instruments ingeniously fashioned to every conceivable requirement of modern surgery sufficed to confirm the reputation for finish and superior workmanship which Messrs. John Weiss and Son's (Oxford-street, W.) goods have justly earned. In regard to tape plasters, Messrs. Leslie and Co. (Walbrook, E.C.) have lately made an important addition to their list in the form of a rubber adhesive strapping which presents many advantages. The well-known excellence of this firm's other dressings is evidently maintained.

The list of the Medical Supply Association (High Holborn, W.C.) included a good assortment of various appliances—as, for example, a combined reading, eye, and throat lamp, improvements in cautery burners, nasal, ear, and eye instruments, &c., while, close by, Messrs. Fassett and Johnson (Snow-hill, E.C.) exhibited their absorbent cottons, lints, gauze, antiseptic dressings, medicated dressings, &c., all of which are well known for their standard uniform and reliable character. The ingenious air-tight aseptic container for medicated bandages is an important introduction of this firm. It consists of wood fibre package incorporated with an antiseptic and coated within with antiseptic lacquer. The joints overlap and are made not only doubly secure by an overlapping label but also air-tight by the entire surface being lacquered. It is compact, durable, and trustworthy. Lastly, the exhibit of Messrs. W. Bartleet and Sons (Gresham-street, E.C.) was chiefly set apart for "surgical needles" of every description.

III.—Special Foods and Food Adjuncts.

As will be seen, this Section comprised a really valuable collection of foods and food aids, not a single exhibit being submitted for inspection which had not in our judgment a distinct claim upon the attention of the practitioner. Let us take, for example, the sterilised preparations of milk of the Aylesbury Dairy Co. (St. Petersburg-place, W.), who now supply sterilised milk in vacuum stoppered bottles, and also humanised milk, the composition and character of which we have already favourably reported upon. This exhibit also included a laboratory, fully equipped with appliances for the examination and analysis of milk, the demonstration of which by the company's chemists was watched with great interest. "Koumiss" and Muffler's sterilised food for infants and invalids were also amongst the excellent products shown by this company. Again, Messrs. Armour (Tooley-street, S.E.) had a well-arranged list of their well-known laboratory products on view, including their standard and reliable preparations of pepsin (powder, granular, scale, and soluble powder), glycerole pepsin, pancreatic powder, and desiccated ox-gall, while as examples of powerful nutrients should be mentioned the palatable wine of beef peptone (1 oz. representing 1 oz. of prime beef), beef peptone paste and powder, concentrated extract of beef, and the not inaptly named preparation "vigoral," containing beef fibre. A satisfactory feature of these preparations is their fresh and meaty flavour.

Messrs. Allen and Hanburys showed their malted infant's food—first food for infants and mother's milk food—in the form of powder, sterilised, and of a composition exactly in accordance with physiological requirements, as we have elsewhere shown. Their well-known malt extract preparations were, it is needless to add, also on view. A great variety of foods eminently adapted for use in diabetes and obesity were submitted for inspection and taste by Messrs Callard (Regent-street, W.). These included a "Parmesan and celery cheese straw," an after-dinner biscuit of really tempting flavour; sponge and almond cakes, affording an agreeable change from the usual dry foods; walnut, hazel-nut, and pine-nut biscuits, belonging to a new series of afternoon tea biscuits; aleuronat (vegetable albumin) biscuits, in imitation of oatmeal biscuits and quite free from starch and sugar; almond meal biscuits, a plain, palatable form of every-day food; and the "Callista" biscuit, recently reported by us as of unquestionable nourishing value, despite the absence of starch, sugar, and butter. This admirable list may be concluded with the mention of the excellent ivory jelly made by this firm, which is so prepared that the phosphates are secured in a perfectly soluble form; it is, therefore, justly urged as valuable for bone-building and for children teething or with rickets. Messrs. Stern (Gray's-inn-road) have recently brought out a nourishing food under the name of "Narissa." Judging from its analysis, it is correctly described as a complete food, containing a high proportion of albumin and phosphates, a suitable amount of fat, and a minimum of starch. In practical use it is spoken of highly. Messrs. Nestlé's (Cannon-street, E.C.) concentrated milk may be confidently used for all the purposes of fresh milk, since it is sterile and contains all the fatty principles of the original milk intact.

The superiority and purity of the digestive ferments prepared by Messrs. Fairchild, Bros., and Foster (New York; London agents, Burroughs, Wellcome, and Co., Snow-hill Buildings) are well known. They have recently introduced some excellent dietetic aids called, respectively, "panopepton" (a palatable bread and beef peptone, containing the edible substance of prime lean beef and best wheat flour, thoroughly cooked, digested, sterilised, and concentrated *in vacuo*); "peptogenic powder" (for peptonising milk and preparing "humanised milk"); and pepsencia (an active digestive essence obtained by direct

Digitized by Google

extraction from the fresh calf rennet). Experiments demonstrating the value of these preparations afforded an interesting feature of this exhibit. Under the curious title "Food Specialists and Medical Comfort Contractors" the Bovril Company (Farringdon-street, E.C.) exhibited their well-known preparations, the original product "Bovril" being now widely esteemed as a cheap, yet pleasant, and undoubtedly comforting and nourishing beverage containing the meat fibre as well as the extractives. Self-digesting "whole meal food" and "best food for infants" are titles which have long been associated with two well-known preparations of Messrs. Savory and Moore (New Bond-street, W.), besides which should be mentioned, although they are equally well known, the peptonised preparations of this firm, which are valuable alike in health and disease.

An interesting dietetic preparation is the Cerebos nutritive table salt of the Cerebos Salt Company (Upper Thames-street, E.C.), which contains, it is said, mixed phosphates in the natural proportions of wheaten bran, and even a minute proportion of calcium fluoride, a normal constituent of the enamel of the teeth. It is a clean white salt, and is considered to be of service in aiding the formation of the bones and teeth. Amongst foods well adapted for infant feeding is Horlick's malted milk, the constituents of which have been carefully modified by the action of diastase to suit the needs of infants and invalids. Its analysis presents the composition of a complete food, rich alike in albuminous and mineral substances, while milk sugar with dextrine are the only carbohydrates present. It is a distinct advantage that this preparation requires no cooking, but is simply to be dissolved in warm water, the resulting fluid closely resembling milk in appearance. Specimens were exhibited by the London agents of 39, Snow-hill, E.C. It is impossible in the space at our disposal to exhaust the list of Messrs. Brand's (Mayfair, W.) specialities for invalids, including their well-known meat essences, but we may mention the albuminous essence of beef, consisting of the juice of the finest beef and containing a portion of the albuminous, fatty, and—important to add—fibrous elements. Brand's meat-juice we have already dealt with at length in a critical and, we may add, satisfactory report emanating from our laboratory.

Similarly we have pointed out the high food value by analysis of Mosquera beef jelly and beef meal, which were amongst the food products shown by Messrs. Parke, Davis, and Co. (North Audley-street, W.)

Amongst the many excellent food preparations placed now at the disposal of medical men must be reckoned the liquid beef peptonoids of Messrs. Carnrick and Co. (Hart-street, Bloomsbury, W.C.), with or without coca; cod-liver oil milk; and a milk-wheat food (soluble food). Each and all are of a remarkably high standard of nutrient value. A satisfactory product, as we have on a previous occasion shown, is the Viking brand of unsweetened condensed milk (Norwegian Milk Condensing Co., Philpot-lane, E.C.). It contains no added sugar, no objectionable preservatives, and a proper proportion of fat, while its flavour is good. The essences, jellies, and meat juices of the Viking Food and Essence Co. (King's-road, St. Pancras) formed an attractive exhibit amongst food specialities and delicacies for invalids, a feature of these preparations being their delicate and pleasant meaty flavour. The merits of the Liquor Carnis Co's. (Farringdon-street, E.C.) preparations have been already emphasised by our own laboratory results as evidenced in their powerful meat juice and in marrol, malto-carnis, and virol. Virol-sans-Sucre—like the last, a preparation of red and yellow bone-marrow, rich in haemoglobin and organic compounds, but free from starch and sugar—is a comparatively recent and important addition to this list of highly nourishing foods, which, further, are in the highest degree palatable. The name of Van Abbot (Duke-street Mansions, Grosvenor-square) is well known in association with diabetic foods, of which an excellent collection was shown, providing the diabetic not only with food which he may eat, but which is also of an agreeable kind. Bran biscuits for constipation, hypophosphite of lime biscuits for delicate children, and obesity biscuits manufactured by the same firm are entitled to an equal meed of praise. As an illustration of the recent advances made in the preparation of condensed milk we may take the specimens shown by the Anglo-Swiss Condensed Milk Company (Mark-lane, E.C.) comprising "ideal milk," not sweetened, but preserved by sterilisation and enriched with 20 per cent. pure cream; ordinary condensed milk containing the cream of the original milk; and, finally, a very palatable preparation of condensed milk with cocoa. Lastly, the preparations and compounds (cod-liver oil, for example) of active malt essences were well represented in the exhibits of Messrs. Allen and Hanburys, Messrs. Burroughs, Wellcome, and Co., the Maltine Co. (Hart-street, Bloomsbury), the Standard Malt Extract Co. (Billiter-street, E.C.), who also exhibited a liquid extract, and the Malto-peptone Co. (Leadenhall-street), who prepare also active malt jellies, with and without cod-liver oil, the obvious advantages of which were only recently pointed out in our Analytical Records (*vide* THE LANCET, April 27th, 1895).

(To be continued.)

THE MUSEUM OF MEDICAL ANTIQUITIES.

THE interesting collection of votive offerings of ancient Italy and surgical instruments brought together by Dr. Luigi Sambon, and exhibited by Messrs. Oppenheimer, Son, and Co., Limited, in the Victoria Rooms of the Savoy Hotel, attracted considerable attention. Certainly the collection was a remarkable one, and Dr. Sambon, who has been commissioned by the Government of Italy to prepare a work on the history of medicine for the next International Medical Congress, deserves great praise for his assiduity in bringing together a series of antiquities that throw considerable light on the history of the healing art. The exhibition may be divided into two parts, one a collection of "donaria" or votive offerings for cures performed or desired, and the other a collection of surgical instruments taken from the ruins of Pompeii and Herculaneum. Some sixteenth and seventeenth century instruments were also shown, and their

rude construction when compared with some of the more ancient was not a little surprising. The donaria consisted of terra-cotta models of almost all parts of the body and tablets showing full-sized figures both individually and in groups. One fine specimen represented a mineral spring, on one side of which stands Hercules (usually associated with hot springs) with both his hands over the region of the bladder, indicating that the water is good for the kidneys &c. The tablet above, of which Dr. Sambon has kindly supplied us with a photograph, is a good type of some of the best of these donaria. It is a votive offering for disease

Digitized by Google

found at the Temple of Maternity, Capua, and is intended to show hypertrophied breasts and abdominal tumour, or perhaps pregnancy.

Some of the smaller offerings were made of bronze, some of silver, and in rare cases of gold. These were nailed to the walls of the temples and shrines. One series of donaria connected with lactation came principally from the Temple of Maternity at Capua and the Minerva Medica in Rome.

The collection of ancient surgical instruments was very interesting. The Roman instruments are remarkable for their simplicity and beauty. In a few cases they are coated with silver, and have on them the names of the medical men to whom they belonged. They are entirely of metal and much better than those used 800 or 900 years ago. The blades of the scalpels and lancets were of iron with handles of bronze, but in most of the instruments the blades have rusted away. Those found in the bed of the Tiber, however, are still intact. The instruments are in great variety and are most ingenious in construction. As they are made of metal, it is easily conceivable how liable they were to slip in the hands of the surgeon, especially when covered with blood, and the device adopted to prevent this (where the instrument lent itself to it) was as ingenious as it was simple. A glance at the accompanying diagram will explain this better than a verbal description. The centre of the instrument was moulded into the form of a ring, and a slight pressure of the index or other finger made the grip quite firm.

Although perhaps remotely connected with the majority of the exhibits, three safety pins and a metal cup-shaped vessel perforated with a number of holes, and containing a cast very much like the half of a lemon, forcibly reminded visitors that "there is no new thing under the sun."

Medical News.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGES OF PHYSICIANS AND SURGEONS.—The following gentlemen passed the First Examinations of the Board in the subjects indicated under the Four Years Regulations:—

Part I.—Chemistry, including Chemical Physics:—

Bell, Victor Samuel Alexander, University of Cambridge and St. Bartholomew's Hospital.
Bennett, Percy Moore Septimus, Middlesex Hospital.
Bulteel, Christopher Herbert Dimond, King's College, London.
Butler, Thomas Langton, St. Mary's Hospital.
Dean, Edmund Clapperton, University College, London.
Hort, Frederick Aylmer, Middlesex Hospital.
King, Thomas Arthur, University of Cambridge and St. Thomas's Hospital.
Lewis, Lewis Evan, University College, Cardiff.
Nicholls, Ernest Albert, London Hospital.
Nicholls, William, St. Bartholomew's Hospital.
Scott, Charles Augustus, Charing-cross Hospital.
Thomas, Elijah Richard Lockwood, London Hospital.
Williams, William Wheldon, University College, London.

Part II.—Materia Medica:—

Andrew, Alfred John, St. Bartholomew's Hospital.
Bennetts, Archibald James, St. Mary's Hospital.
Brundrett, Gilbert Thomas, Owens College, Manchester.
Collingwood, Percy Hilderbrand, St. Thomas's Hospital.
Davies, William John Edwin, St. Thomas's Hospital.
Dean, Edmund Clapperton, University College, London.
Dring, Henry George Carpenter, St. Bartholomew's Hospital.
Du Heaume, Ernest Philippe, St. Bartholomew's Hospital.
Ellis, Richard Thomas, Yorkshire College, Leeds.
Gayner, John Stansfield, St. Bartholomew's Hospital.
Good, Hardman Allgood, King's College Hospital.
Grüber, Parkinson Osborne, St. Bartholomew's Hospital.
Hatfield, John Rayner, Yorkshire College, Leeds.
Hay, William Leslie, King's College, London.
Hayes, Arthur John, Middlesex Hospital.
Holman, Thomas Edward, Guy's Hospital.
Howells, John, London Hospital.
Iliffe, Caris William, Owens College, Manchester.
Jones, Alfred, London Hospital.
King, Neville Pearce, Charing-cross Hospital.
Knowlton, Alexander John, Middlesex Hospital.
Langworthy, Edward Southwood, St. George's Hospital.
Leary, George Edward, Mason College, Birmingham.
Longhurst, Ernest Thomas, St. Mary's Hospital.
Maskew, Charles Henry, Mason College, Birmingham.
Mitchell, William Grant, Guy's Hospital.
Nicholls, William, St. Bartholomew's Hospital.
Nimmo, Frank Hutton, St. Bartholomew's Hospital.
Pomeroy, Edward Hugh, Guy's Hospital.
Porteous, Herbert Llewellyn, Middlesex Hospital.
Pugh, Charles Grant, Middlesex Hospital.
Quirke, Edwin Alphonsus, Mason College, Birmingham.
Ransford, Sydenham Least Gifford, St. Mary's Hospital.
Rouillard, Jean Antoine Abel, St. Thomas's Hospital.
Scott, Charles Augustus, Charing-cross Hospital.
Smith, Arthur Lionel Hall, University College, London.
Square, Arthur Powell, Middlesex Hospital.
Stratton, Percy Haughton, Mason College, Birmingham.
Thornton, George Lestock, St. George's Hospital.
White, Alfred Skeate, Ledwich School, Dublin.
Wood, Jacob Medley, Middlesex Hospital.
Woodstock, Charles Percy, Anderson's College, Glasgow.
Woollcombe, Alfred, St. Bartholomew's Hospital.

Part III.—Elementary Anatomy and Elementary Physiology:—

Brundrett, Gilbert Thomas, Owens College, Manchester.
Bulteel, Christopher Herbert Dimond, King's College, London.
Dean, Edmund Clapperton, University College, London.
Dowling, Stanislaus Marcus, Catholic University of Ireland, Dublin.
Evans, John, St. George's Hospital.
Hawkins, Arthur, University of Cambridge and St. Bartholomew's Hospital.
Hey, Samuel, University of Cambridge and St. Bartholomew's Hospital.
King, Thomas Arthur, University of Cambridge and St. Thomas's Hospital.
Marsden, Walter, Yorkshire College, Leeds.
Mayor, Hamlet Horace, Owens College, Manchester.
Mort, James Henry, University of Cambridge.
Nicholson, Guy Berners, University of Cambridge.
Sanders, Charles Henry, St. George's Hospital.
Simpson, Fred Algernon, University of Cambridge and St. Mary's Hospital.
Walker, Georges Charles, University College, Liverpool.

Elementary Physiology only:—

McCarthy, Tom, Queen's College, Cork.

THE ASSOCIATION OF BRITISH POSTAL MEDICAL OFFICERS.—The annual general meeting and conference of this association were held on July 31st in the Hôtel Métropole, London, Dr. John Watson, the Vice-President, occupying the chair in the unavoidable absence of the President, Mr. Frank Iliffe. There was a large attendance of members. The secretarial report exhibited a persistent and encouraging increase in the membership, and in the subsequent discussion the opinion was expressed by those present that it should be clearly intimated to those who are still non-members that admission into the association in the near future would be attended by considerable difficulty. Several important matters were brought under discussion, but the reading of a paper by Dr. Giddings on the subject of How much should Postal Medical Officers be influenced by Heredity in examining Candidates for the Postal Service was postponed on account of the numerous engagements connected with the meeting of the British Medical Association. The following executive was elected for the ensuing year:—President: Mr. Matthew C. Halton, J.P., M.R.C.S., Ex-Mayor of Barnsley. Vice-Presidents: Mr. Frank Iliffe, M.R.C.S., Derby; and Mr. John Watson, M.D., Manchester. Honorary Secretary in Scotland: Mr. W. Dougan, M.D., Glasgow. Honorary Secretary in Ireland: Mr. H. Fitz-Gibbon, M.D., Dublin. Honorary General Secretary and Treasurer: Mr. R. Ritchie Giddings, M.B., Nottingham. Executive Committee: Mr. Edwin L. Adeney, J.P., M.D., Tunbridge Wells; Mr. J. Walton Browne, M.D., Belfast; Mr. Matthew Coates, M.D., London; Mr. W. Hugh Hughes, J.P., M.R.C.S., Ashton-under-Lyne; Mr. W. Husband, M.R.C.S., Manchester; Mr. Bertram Thornton, J.P., M.R.C.S., Margate; and Mr. S. Walker, M.R.C.S., Middlesbrough. Auditors: Mr. W. Dougan, M.D., Glasgow, and Mr. T. West Symes, M.D., Halifax. In the evening the annual banquet took place in the Whitehall Rooms and was a very great success, Mr. Frank Iliffe, the President, being in the chair.

Digitized by Google

SUPERANNUATION ALLOWANCE.—Mr. Edward Marshall, M.R.C.S., late medical officer of the Mitcham Schools, Surrey, has been granted a superannuation allowance of £66 13*s.* 4*d.* per annum.

LITERARY INTELLIGENCE.—Messrs. Chapman and Hall have been constituted sole agents in this country, the Continent, and the Colonies for the sale of the important scientific and technological publications of Messrs. Wiley and Sons of New York.

BRITISH LARYNGOLOGICAL, RHINOLOGICAL, AND OTOLOGICAL ASSOCIATION, 1895-96.—The following is the list of office-bearers elected on July 25th, 1895:—President: Mr. Geo. Stoker (London). Vice-Presidents: Dr. Ed. Law, Dr. Middlemass Hunt (Liverpool), and Dr. Wm. Milligan (Manchester). Council: Metropolitan—Dr. W. McNeil Whistler (*ex-officio*), Dr. Dundas Grant, Mr. Mayo Collier, Mr. Wyatt Wingrave, and Mr. G. C. Wilkin; Extra-Metropolitan—Dr. J. M. E. Scatliff (Brighton) and Mr. John Bark (Liverpool). Hon. Sec.: Dr. Pegler.

PRESENTATION.—Dr. A. S. Merrick, resident medical superintendent of the Belfast District Lunatic Asylum, was the recipient, on the 7th inst., of an address and a silver salver, as mementoes of his long period of service in the institution. The Rev. N. E. Smith, by request, made the presentation. He said that he had known Dr. Merrick for twenty years. No one had been more successful in the management of such an important institution. The presentation was not one on leave-taking or of departure. They trusted Dr. Merrick would long remain with them, that while as years went on the ties that now bound them together would become more closely knit.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The New Parliament.

THE new Parliament met for the first time on Monday, Aug. 12th, when there was a good attendance both of Lords and Commons. The latter elected Mr. Gully again as their Speaker, and next day Her Majesty the Queen signified approval of the election. Two days being occupied with the swearing-in of members, the Queen's Speech was not read until Thursday, Aug. 15th.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.

ADAMS, J. D., M.D. St. And., M.R.C.S., has been appointed Medical Officer of Health to the Long Ashton Rural District Council.

BAILEY, THOS. R., M.D., C.M. Edin., has been appointed Medical Officer of Health to the Bilston District Council.

BARCROFT, A. E. I., L.K.Q.C.P., L.R.C.S. Irel., has been appointed Medical Officer for the Myddle and Baschurch Sanitary District of the Ellesmere Union.

BEATTIE, R., M.D., M.Ch. Irel., M.R.C.S., has been appointed Medical Officer of Health for the Toothill Upper Urban Sanitary District, vice Brown, resigned.

BIGGAM, JOHN, M.D., C.M. Edin., has been appointed Medical Officer of Health to the Sedgeley District Council.

BOND, N. T., M.B., C.M. Edin., has been appointed Medical Officer for the No. 4 Sanitary District of the Liskeard Union.

BOND, W. A., M.D., B.C., D.P.H. Camb., M.R.C.P. Lond., has been appointed Medical Officer of Health for the Holborn District Board.

BREDIN, J. N., L.R.C.P., L.R.C.S. Irel., has been appointed Medical Officer for the Polton Sanitary District of the Biggleswade Union.

BROWN, WILLIAM, M.D., C.M. Glasg., has been appointed Medical Officer of Health for the Stapleton District Council.

BYASS, E. S., M.B., C.M., L.R.C.S. Edin., has been appointed Medical Officer for the Slangham Sanitary District of the Cuckfield Union.

CAREY, WM., L.R.C.S., L.M. Irel., has been appointed Medical Officer for the Workhouse and the Holbrook Sanitary District of the Sawford Union.

COATES, RICHARD, L.R.C.P., M.R.C.S., has been appointed Resident Medical Officer to the Newport and Monmouthire Infirmary, vice S. H. Lee, resigned.

CROUCH, C. P., M.B. Lond., F.R.C.S., has been appointed Honorary Medical Officer to the Weston-super-Mare Hospital, vice Alford, deceased.

FOSTER, WM., M.B., D.P.H. Camb., M.R.C.S., has been appointed Medical Officer of Health to the Shipley District Council.

GARSTANG, T. W. H., M.R.C.S., has been appointed Medical Officer of Health to the Knutsford Urban District Council.

GILPIN, R. H., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer of Health to the Petworth Rural District Council.

GREGOR, A., M.B., C.M. Aberd., has been appointed Medical Officer for the Sutton-on-Trent Sanitary District of the Southwell Union.

HARAN, J. A., M.B., B.Ch. Dub., has been appointed Resident Medical Officer for Barrington's Hospital, Limerick, vice Mulcahy.

HASWELL, J. F., M.B., C.M. Edin., M.R.C.S., has been appointed Medical Officer of Heath to the Penrith Rural District Council.

HIND, ALBERT, L.R.C.S., L.M. Edin., has been appointed Medical Officer of Health to the Southampton Town Council.

JOHNSON, F., L.R.C.P. Irel., M.R.C.S., has been appointed Medical Officer for Hedgerley by the Eton Rural District Council.

JOHNSTONE, J. L., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the Upholland Sanitary District of the Wigan Union.

JONES, H. T., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer of Health to the Pembroke Rural District Council.

JONES, R. D., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the Grangetown Sanitary District of the Cardiff Union.

MORISON, JOHN, M.D. Edin., M.R.C.S., D.P.H. Camb., has been reappointed Medical Officer of Health and Public Analyst for St. Albans City.

NEWTON, R. F., L.R.C.P. Lond., M.R.C.S., has been appointed Medica Officer for the No. 2 Balcombe Sanitary District of the Cuckfield Union.

PARSONS, G. G., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the Fourth Sanitary District of the Westbury and Whorwellsdown Union.

PURDY, Jas. R., M.B., M.S. Aberd., has been appointed Medical Officer of Health to the Hull County Council.

ROYDS, W. A. S., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the St. Mary Bowine Sanitary District of the Whitchurch (Hants) Union.

SANDFORD, F. J., M.D. St. And., M.R.C.S., has been appointed Medical Officer of Health for the Drayton and Titterby Rural Sanitary Districts.

SANDFORD, G. CALROW, M.B., has been appointed Resident Obstetric Surgeon to the Dispensary, York.

SENIOR, ARTHUR, M.B., B.S. Camb., has been appointed Medical Officer of Health to the Kingston and the Dittons Urban District Council.

STUBB, E. C., F.R.C.S., has been appointed Assistant in the Throat Department of St. Thomas's Hospital.

THOMPSON, W. H., M.D. Durh., L.R.C.P., L.M., L.R.C.S. Edin., has been appointed Medical Officer of Health to the Quarry Bank Urban District Council.

TURNER, J. A., M.B., C.M. Edin., D.P.H. Camb., has been reappointed Medical Officer of Health for Lutterworth.

WEEKS, C. F., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed Medical Officer for the Pinchbeck Sanitary District of the Spalding Union.

WHITTINGTON, S.P., L.R.C.P., L.M., L.R.C.S. Edin., has been appointed Medical Officer of Health to the Neath Rural District Council.

WYCHE, E. M., M.R.C.S., L.R.C.P., has been appointed Assistant Medical Officer to the Infirmary of the City of London, Bow-road, E

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

CITY ASYLUM, Birmingham.—Clinical Assistant. Board and lodging provided.

CONVALESCENT FEVER HOSPITAL, Gore Farm, Darenth, Kent.—Dispenser. Salary, £5 a month, with board, lodging, and washing. Applications to the Medical Superintendent at the hospital.

GENERAL HOSPITAL FOR SICK CHILDREN, Pendlebury, Manchester.—Junior Resident Medical Officer, for one year. Salary £80 per annum, with board and lodging.

GENERAL HOSPITAL, Nottingham.—House Physician, for two years. Salary £100, rising £10 a year to £120. Also Assistant House Surgeon, for six months. Board, lodging, and washing in the hospital provided.

Digitized by Google

GLAMORGAN COUNTY ASYLUM, near Brigend.—Junior Assistant Medical Officer. Salary £130, rising £10 a year to £150, if approved, with with board (no beer or wine), lodging, and washing.

MIDHURST UNION, Sussex.—Medical Officer for the Union Workhouse, situate at Easebourne, near Midhurst. Salary £30 per annum, with extra fees for midwifery cases. Applications to the Clerk, Midhurst

NORFOLK AND NORWICH HOSPITAL.—Assistant to House Surgeon, for six months. Board, lodging, and washing provided.

ROYAL SOUTHERN HOSPITAL, Liverpool.—Third House Surgeon. Salary £65 per annum, with board, lodging, and laundry.

STAFFORDSHIRE GENERAL INFIRMARY.—Assistant House Surgeon. Salary £30 per annum, with board, lodging, washing, &c.

THE COUNCIL FOR THE BOSTON RURAL DISTRICT.—Medical Officer of Health for the District, for five years. Salary £110 inclusive. Applications to the Clerk of the Council, 10, New-street, Boston.

WEST RIDING ASYLUM, Wadsley, near Sheffield.—Fifth Assistant Medical Officer. Salary £100 per annum, rising £10 a year up to £150, with board, &c.

Births, Marriages, and Deaths.

BIRTHS.

AITKEN.—At Craigard, High-road, Ilford, on Aug. 10th, the wife of James Aitken, M.D., of a son.

BOURNE.—On Aug. 7th, at Abbotsfield, Kenilworth, Warwickshire, the wife of Edmund Kemp Bourne, M.D. Ed., of a son.

CAPPER.—On Aug. 13th, at Tunbridge Wells, the wife of Percy Capper, M.B. Edin., of a son.

CUTTING.—On Aug. 11th, at Chetwynd House, Stalham, Norfolk, the wife of Ernest Buxton Cutting, M.R.C.S., L.R.C.P., of a son.

GODSON.—On Aug. 12th, at Sharsted, Westgate-on-Sea, the wife of Clement Godson, M.D. Aberd., C.M., of Grosvenor-street, London, of a son.

PARTRIDGE.—On Aug. 10th, at Albany-road, Camberwell, S.E., the wife of W. T. Partridge, M.R.C.S., L.R.C.P., of a son.

ROSS.—On July 25th, at Rio Tinto, Spain, the wife of R. Russell Ross, M.B. Edin., of a daughter.

RUSSELL.—On Aug. 9th, at Plas Ian Alltran, Holyhead, the wife of William Fox Russell, M.B. Dub., of a daughter.

WAKE.—On Aug. 10th, at Dartmouth-park hill, N.W., the wife of Chas. Hereward Wake, M.R.C.S., L.R.C.P., of a son.

WESTLAKE.—On Aug. 7th, at Victoria-street, Great Grimsby, Lincolnshire, the wife of Algernon Westlake, M.B. Edin., of a daughter.

WOOLLCOMBE.—On Aug. 6th, at the Crescent, Plymouth, the wife of Walter L. Woollcombe, F.R.C.S. Ed., of a daughter.

WOOLLETT.—On Aug. 5th, at Wymering House, Southwold, Suffolk, the wife of Sidney Winslow Woollett, M.R.C.S., of a son.

YEOMAN.—On Aug. 10th, at Clark's Hill, Prestwich, Manchester, the wife of Stanley Yeoman, M.B. Cantab., of a daughter.

MARRIAGES.

ANDERSON—TETLEY.—On Aug. 6th, at St. Chad's Church, Far Headingley, Leeds, William Anderson, F.R.C.S., of St. Thomas's Hospital, to Louisa, third daughter of the late F. W. Tetley, of Fox Hill, Westwood, Leeds.

WICKHAM—WATKINSON.—On Aug. 7th, at the parish church, Huddersfield, Charles A. Wickham, L.R.C.P., L.R.C.S. Edin., of Elmlea, Willesborough, Kent, to Marion Cassie Watkinson, eldest daughter of Thos. Bond Watkinson, Esq., of Beechwood, Huddersfield.

WRIGHT—GRAY-WILLIAMS.—On Aug. 7th, at Christ Church, Bootle, Willie Eustace Merle Wright, L.R.C.P., L.R.C.S. Ed., to Mary (Minnie) Gray-Williams.

DEATHS.

HARRIS.—On Aug. 5th, at the Medical Superintendent's House, Infirmary, East Dulwich, Ruth Elwin, only child of Herbert Elwin and Edith Harris, aged 1 year 9 months.

NEWLAND.—On Aug. 8th, at his residence, Raglan-road, Dublin, Robert Newland, M.D., in his 79th year.

ROBBS.—On Aug. 13th, at Bournemouth, William Edward Robbs, M.B. Lond., J.P., of Powis-square, W., aged 64 years.

STRATTON.—On Aug. 8th, at Nevern-square, S.W., Brigade-Surgeon John Proudfoot Stratton, M.D. Aberd., Indian Medical Service (Retired), aged 66.

WELCH.—On Aug. 7th, at Hackney-road, Charles Welch, L.R.C.P. Ed., M.R.C.S., in his 77th year.

YELDHAM.—On Aug. 10th, at St. Leonards-on-Sea, Stephen Yeldham M.D., M.R.C.S., in his 85th year.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

EDITORIAL NOTICE.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICE.

"THE LANCET" AND ACCIDENT INSURANCE.

A LITHOGRAPHED CIRCULAR LETTER, emanating from an office in the Strand district, is being sent to members of the medical profession, offering to supply them with THE LANCET, in conjunction with an accident insurance policy. The Proprietors of THE LANCET are in no way connected with the scheme (of which they cannot approve), and were not aware of its inception until their attention was called to it by a reader who had received the circular.

"A NEW APPOINTMENT AT THE MIDDLESEX HOSPITAL."

IN our issue of last week we commented upon certain remarks which had appeared in the lay press relative to the recent appointment at the Middlesex Hospital. At the same time we expressed our assurance that the paragraph in question had been inserted without the knowledge or leave of the subject of it. We have received confirmation of this view from the gentleman in question, who remarks in addition that the paragraph was grossly incorrect. It is hard that a medical man should have to suffer from such an annoyance, and he has our sympathy.

Mr. Lennox Browne.—We have referred the suggested correction to our reporter, who finds that it constitutes a fuller account, but not a different one from that which we have published, while it leaves untouched points to which reference was made.

"THE DANGERS OF COCAINE."

To the Editors of THE LANCET.

SIRS,—Since reading your annotation on the "Dangers of Cocaine" in THE LANCET of July 6th I have had a case which illustrates the haphazard way in which this drug is used.

I was called in by a dentist to see a patient who, I found, had the following symptoms. She was unconscious and almost pulseless, respiration rapid, pupil dilated and fixed, and there was absence of conjunctival reflex. The dentist stated that he had injected cocaine and extracted two teeth. On being asked how much cocaine he had used, he said "one tabloid," and on referring to his stock he found that each tabloid contained half a grain. He stated that he was convinced that the collapse was not caused by cocaine, as he had recently used a hypodermic injection of seven tabloids (3½ gr.) in another case. The patient slowly recovered consciousness after hypodermic injections of ether and inhalation of nitrite of amyl, but suffered during the rest of that day and the next from giddiness, headache, and general lassitude. The dentist, she stated, had advised cocaine. She suggested that he should have a medical man present, as she believed she had a weak heart. The dentist assured her that it was not at all necessary, as there was no danger associated with cocaine.

I am, Sirs, yours faithfully,

Aug. 12th, 1895. J. J. WALLACE, M.B.R.U.I.

UNQUALIFIED PRACTICE.

To the Editors of THE LANCET.

SIRS,—After six years spent in a distant colony I have just returned to my native land expecting to find certain abuses swept away, and that owing to the disappearance of the unqualified assistant more scope for the duly registered man would be found. During the few days I have spent in England, however, my hopes have received some rude shocks; for although a system of careful "covering" is followed, yet unqualified practice seems to be carried on to as great an extent as ever it was. It is not so much the case of the hard-working general practitioner who keeps an assistant to do his dispensing and attend to trivial cases at the surgery of which I complain, as the case of the gentleman who, having been in good practice for a great many years and having the outward signs of prosperity, holding good county appointments and even high office under what should be our greatest protecting association—it is against the style of practitioners whom one might reasonably expect to set a worthy example to other members of the profession that my complaint is directed: one who lives in semi-retirement and keeps his assistant down the street to do midwifery and night work and can be trusted to call in his principal in time to sign the death certificate. In the colony in which I have been resident the unqualified assistant does not exist. Quacks abound, but they dare not pass themselves off as medical men, and it seems to me that the business of these men is honest and straightforward in comparison with that above alluded to.

Is it not a burning shame, Sirs, that men who have worked hard and spent large sums of money in passing examinations should be driven out of their own country owing to this unfair form of competition? I trust we shall see an agitation started which will not cease until the unqualified assistant entirely disappears from our midst.

I remain, Sirs, your obedient servant,

July 23rd, 1895. JUSTITIA.

*** Our correspondent details a procedure against which the General Medical Council is always ready to act. We are not ignorant that improper use is still made of unqualified assistance; we regret it, and may be depended upon always to do our best to check it. The particular methods alluded to by our correspondent would meet with the condignest punishment at the hands of the General Medical Council if its occurrence were duly authenticated before them.—ED. L.

"THE TITLE OF 'DR.'"

To the Editors of THE LANCET.

SIRS,—Many medical men can doubtless sympathise with "M.D." in his amusement at the "title of 'Dr.' question," as well as in his defence of his old university. Degrees and diplomas must differ under the present cumbrous twenty-barrelled examining system; but invidious comparison can only succeed in "fouling our own nest." Though the question is amusing to "M.D.," to me it is irritating. It is not exactly a sore, but it is a chronic desquamation with a tendency to itching. Why should it not be settled once for all? This could be done (1) by a consensus of the qualifying bodies, or (2) by obtaining the highest legal opinion, or (3) by means of a friendly legal action, the expense of which could be defrayed by subscription. I have repeatedly contended in your columns that the title is one of courtesy, and the using or not a matter of personal taste guided by prevailing customs and ancient usage. In so contending I have expressed my own opinion, but have always been open to correction and willing to allow to others the same freedom of judgment on a point as yet undecided. If my suggestion should lead to a final decision future irritation may be avoided, and the medical "odium" of boasting and depreciation with regard to degrees and diplomas may at least be mitigated. I am, Sirs, your obedient servant,

Loughborough, Aug. 9th, 1895. J. B. PIKE.

To the Editors of THE LANCET.

SIRS,—I hold the diplomas of the Conjoint Board and am also a Doctor of Philosophy of —— University. Am I at liberty to style myself Dr. A—— B—— on my door-plate?

I am, Sirs, your faithfully,

A—— B——.

*** We think not. The non-medical degree is quite a creditable one, but should not be prefixed to the name on a door-plate, presumably displayed for professional purposes. We refer to this query in a leading article in our present issue (vide p. 412).—ED. L.

PROPER FACILITIES TO THE CORONER.

To the Editors of THE LANCET.

SIRS,—Is the medical man bound to answer questions asked by the coroner previously to an inquest without being summoned? Or can he legally refuse to give any information relative to the case until he is summoned to do so at the inquest?—I am, Sirs, yours faithfully,

Aug. 12th, 1895. MEDICUS.

*** A witness is not bound to answer any questions until he is summoned and is present in court; but a medical man would be very ill-advised not to give a coroner previously to the inquest every proper information within his power.—ED. L.

ALCOHOLISM *versus* PARACHUTISM.

To the Editors of THE LANCET.

SIRS,—From an annotation in THE LANCET of Aug. 10th, p. 340, I see that a Congress for combating the Abuse of Alcoholic Liquors is to be held at Bâle, where the subject is to be dealt with "not so much by extremists who see nothing but evil in alcohol, as by those who can separate the use of it from the abuse"; also that in Bâle in 1893 of the deaths of males between the ages of forty and fifty "every fourth man died of drink." On p. 343 you allude to the fatal parachute accident at Peterborough, and have no difficulty in concluding that "this sort of exhibition ought not to be allowed. The making of money out of a morbid propensity on the part of people ..... should be made a punishable offence," and you heartily approve of the rider of the jury: "That since no useful purpose is served by these senseless exhibitions ..... they should be made illegal." These two paragraphs lead me to ask, in all humility: 1. Is taking people's money for gratifying their "morbid propensity" in the direction of parachute descents any worse than taking their money for gratifying their "morbid propensity" for alcoholic excitation? 2. In relative cost and consequence is not the "morbid propensity" for alcohol a hundred thousand times worse than that for parachute descents? 3. If these are to be made illegal because they involve risks and are devoid of utility, is not the public sale of alcoholic liquors condemned by the same proposition? 4. Is a "conference" on alcoholism on the lines given by you not as much a foregone conclusion as would be a "conference" on parachute descents by those already committed to parachutism?—I am, Sirs, yours faithfully,

Aug. 12th, 1895. C. S.

*** We have a feeling that our correspondent is pledged to regard the temperance question from one point of view, so that it is not likely that he will be free to see things as we see them. But we answer his queries:—1. The gratification of one morbid propensity is as wrong as the gratification of another. But all use of alcohol is not morbid or practically purposeless; while all gaping at exhibitions whose single interest arises from their danger to another's life is both morbid and practically purposeless. 2. In our opinion, no. The relative costs or consequences are difficult of estimation when we think for a moment of the number of persons using alcohol compared with the number of parachutists. It is not very clear what our correspondent means here by "morbid propensity." Drunkenness costs a people a great deal in moral and material wealth, but that is denied by no one. 3. Certainly the public sale of alcoholic liquors is not condemned or condemnable by the comparison we are asked to institute. 4. We desire to credit those workers at the temperance question who do not see in total abstention the only solution with impartiality and quite as much ability to understand facts, foresee difficulties, or draw conclusions as is claimed for the complete teetotal party.—ED. L.

F.R.C.S.—The quack in question so far protects himself by pretending to be only an M.D. of the United States. As such the General Medical Council has no control over him or his ways. If the Public Prosecutor or the police did their duty such a fraud would not be allowed to go unpunished.

Dr. F. P. Atkinson is thanked for his communication.

THE TENURE OF THE APPOINTMENT OF A POOR-LAW MEDICAL OFFICER.

To the Editors of THE LANCET.

SIRS,—Must the appointment of a Poor-law Medical Officer, if not resident in the parish, be limited to one year? and if limitation exists, why so? I am, Sirs, yours faithfully,

Aug. 13th, 1895. INQUIRER.

*** The Medical Appointments Order, May 25th, 1857, Article 4, enacts that "if the guardians shall elect a district medical officer ..... not residing within his district ..... the guardians shall employ as a district medical officer such person not residing within his district ..... for such time only as the Poor-law board shall approve of or direct." This does not apply to London, and the reason for the provision for re-election seems to be that there must be a point where non-residence would make the officer useless, and the necessity of submitting himself from time to time for re-election would preclude this difficulty. The usual practice of a board is to sanction the employment for a period of three years only.—ED. L.

A QUERY.

To the Editors of THE LANCET.

SIRS,—Will some of your readers kindly inform a middle-aged practitioner where he can be suitably coached or instructed theoretically and clinically during a course of some nine or twelve months for the final M.B. Examination of the London University?

I am, Sirs, yours faithfully,

Aug. 12th, 1895. CIVIS COLONIÆ.

CONSULTATIONS IN CLUB PRACTICE.

To the Editors of THE LANCET.

SIRS,—I am attending a club patient and have attended him for nine weeks; he is getting better and has had a good deal of attendance. At the end of that time his employers, large manufacturers, write asking me if I will meet their medical man in consultation over the case. I meet him, and send in my account to them for that consultation. I have a letter from them two days after expressing their surprise at my making any charge whatever. I should be extremely obliged if you will tell me whether I am right in exacting a fee from them.

I am, Sirs, yours faithfully,

Aug. 13th, 1895. M.R.C.S.

*** Our correspondent is certainly right, on the facts as stated to us, in demanding a fee for the consultation. Such a consultation formed no part of the routine of his club practice, and was, we presume, undertaken entirely in the interests and at the instigation of the patient's employers.—ED. L.

R.—So many union appointments are held and their duties efficiently discharged by gentlemen who for one reason or another are compelled to live far from the centre of their districts that we do not think our correspondent can found any strong claim to the post occupied by a fellow practitioner on the plea of greater geographical convenience; but if real hardship has arisen to the poor, the guardians should know, and should know what to do. We cannot recommend our correspondent to take any active steps in the direction himself.

THE MEDICAL DIGEST.

To the Editors of THE LANCET.

SIRS,—In THE LANCET of July 13th, 1895, p. 92, a case of persistent hiccough is reported to be cured by the use of snuff; and at p. 93 the coryza caused by iodide of potassium is reported as preventable by the simultaneous exhibition of tincture of belladonna. In both instances the remedy is so described as to suggest that it is an original idea. In the "Medical Digest," Section 962:5, the value of sternutatories in hiccough was described in 1886, as well as the value of tickling the nostrils. The use of belladonna in counteracting the ill-effects of iodide of potassium was known in 1885, as a reference to Section 253:2 of the Digest will show.

I am, Sirs, yours truly,

Boundary-road, N.W., Aug. 9th, 1895. RICHARD NEALE, M.D. Lond.

C. L. G. M.—It is usual for the graduates of the Edinburgh schools to affix "Ed." or "Edin." to their abbreviated titles. There is no official list of abbreviations, so that there is no right or wrong in the matter; but to affix "E." only is to breed confusion. In the particular instance given by our correspondent no confusion can arise, for there is no need for such an affix as "M.R.C.S.E.," the Royal College of Surgeons of Edinburgh not bestowing membership.

WANTED SUGGESTIONS FOR TREATMENT.

To the Editors of THE LANCET.

SIRS,—I want suggestions for the treatments of a case of obstinate and long-continued constipation. All sorts of drugs have been tried, also faradaism and massage. The chief symptoms are occasional, sometimes extreme, flatulence; mucoid, jelly-like material hawked up at times; sometimes heart-burn; stools generally hard and dry, generally dark in colour, sometimes too light, very rarely quite normal, when immediate amelioration of symptoms follows; very good appetite, but no proper assimilation of food; complexion sallow, habit of body spare. I shall be very much obliged if you can find a corner for this, and if any of your readers can give me the information I require.

I am, Sirs, yours faithfully,

Aug. 12th, 1895. M.D.

Nurse Alice.—Our correspondent will find in the Medical Directory the information she desires. We cannot recommend any particular place to her.

R. G. J., Capt. S., and *X. Y. Z.*—We do not prescribe, recommend treatment, or suggest the names of individual practitioners.

TALC SHIELD PROTECTOR IN DIPHTHERITIC CASES.

To the Editors of THE LANCET.

SIRS,—Dr. Dowding's ingenious contrivance of talc shield associated with tongue depressor as a protector of the operator in diphtheritic cases, figured in THE LANCET of Aug. 3rd, suggests even a more simple contrivance—namely, a circular piece of talc about three inches in diameter, pierced in the centre by a small flat button with screw or socket end, into which should be passed a stem of vulcanite or other light substance, flattened at the end, to be held in the operator's mouth during examination &c. Both nose and mouth would thus be protected, and perfect freedom in the use of instruments secured.

I am, Sirs, yours faithfully,

Brighton, Aug. 12th, 1895. J. DENNANT, L.D.S. Eng.

GERMAN UNIVERSITY DEGREES.

Medicus would have to pass his examinations in Germany, but if practice in that country is contemplated the mere M.D. of a German university would be of no more use than an English degree. The State Examination, which is severe, must be passed, and if leave is granted, as it generally is, residence at a German university is unnecessary.

A Registered Student in Medicine should consult the physicians of the hospital at which he is studying.

ERRATUM.—In the list of successful candidates for the D.P.H. Lond., published on page 383 of our last issue, the name of one of the successful candidates was not "Wm. Wyatt Shrubsall," but *W. W. Shrubshall.*

METEOROLOGICAL READINGS.

(Taken daily at 8.30 a.m. by Steward's Instruments.)

REPORT OF THE ACADÉMIE DE MÉDECINE OF FRANCE.

Apollinaris

"THE QUEEN OF TABLE WATERS."

"The results of the recent investigations "in Paris and the Report of the Académie "de Médecine of France have placed "Apollinaris Water at the head of all the "waters examined for purity and freedom "from disease germs."

MISTURA CASCARÆ SAGRADÆ COMP.

Prepared from Selected Barks of RHAMNUS PURSHIANA and RHAMNUS FRANGULA, flavoured with AROMATIC SYRUP. *DOSE*— ʒ i. to ʒ iv.

To obtain the best results from the Barks of Rhamnus Purshiana and Frangula it is necessary that they should be collected, not only at the right season of the year but of the proper age, when the bark is neither too young nor too old. Much of that sent to this country consists of bark of all ages, and is consequently not always to be relied upon. In preparing our Mistura Cascaræ Comp. we use only that bark which has arrived at proper maturity, thus ensuring the best results; the menstruum employed being the most suitable for extracting the aperient properties of the bark without causing precipitation when diluted. It is agreeably flavoured with Aromatic Syrup and forms an excellent remedy for Habitual Constipation when continued in doses of ʒ i.; or as an aperient or cathartic, in doses of ʒ ii. to ʒ iv.

"The value of Cascara Sagrada is now very generally recognised. Mackey, Mackey & Co.'s Mistura Cascaræ Sagradæ is evidently prepared from the finest selected material, and we confidently commend this excellent preparation to the notice of the profession."—THE LANCET, Aug. 29th, 1891.

PREPARED ONLY BY

MACKEY, MACKEY & CO., Wholesale Druggists and Manufacturing Chemists,

Please note Change of Address—175, GRANGE ROAD, BERMONDSEY, S.E.

THYROID EXTRACT

(FOR MYXŒDEMA).

A Glycerine Extract of fresh Thyroid Glands, uniform in strength. Prepared from healthy glands, selected under veterinary supervision. A permanent preparation not liable to decomposition. Well suited for internal administration. A certain remedy for the hitherto inevitably fatal Myxœdema. Useful in Goitre, Cretinism, &c. Found very successful in the treatment of Psoriasis (see BRIT. MED. JOURNAL, Oct. 28th, 1893, page 933). Exerts a wonderful effect on the nutrition of the skin, and hence deserves wide trial in skin diseases. Promotes the growth of the hair and may prove of use in baldness of some kinds.

Price 3s., in 1-oz. stoppered bottles. *Dose*—mx. to ʒj.

THYROIDINE, containing the active principle of the Thyroid Glands of the sheep, 4 grains equal to about one-eighth of a fresh gland. Also PILLS and TABLETS, each containing a dose of Thyroidine.

In bottles, 2s. 6d. each.

WILLOWS, FRANCIS & BUTLER, Wholesale & Manufacturing Chemists & Export Druggists,

ESTABLISHED 1751.] 101, HIGH HOLBORN, LONDON.

AWARDS.

GOLD MEDAL, International Health Exhibition, London, 1884.
FIRST ORDER OF MERIT AND MEDAL (Highest Award), Adelaide, 1887.
HIGHEST AWARD, Medical and Sanitary Exhibition, London, 1882.
FIRST ORDER OF MERIT AND MEDAL, Melbourne, 1888.

Liquor Pancreaticus (Benger).

For the preparation of peptonised or partially digested milk and other articles of food.

Simple directions for use enclosed. In 4 oz., 8 oz., and 16 oz. Bottles.

The *British Medical Journal* of April 1st, 1882, in an article on Benger's Preparations, says:—"Time and use have justified the claims put forward for these preparations."

The *London Medical Record* of March 15th, 1882, says:—"These are undoubtedly a great advance on any previous attempt in this direction. . . . The introduction of these preparations is a distinct advance in therapeutics."

The *Medical Times and Gazette* of September 8th, 1883, says:—"Benger's Preparations have deservedly a very high reputation, and are all largely used."

Liquor Pepticus (Benger).

An exceedingly active fluid pepsine, without disagreeable taste.

DOSE.—One or two teaspoonfuls with meals. In 4 oz., 8 oz., and 16 oz. Bottles.

Benger's Peptonised Beef Jelly.

A delicious quick restorative for Invalids and the Aged. In patent glass jars, no metallic contamination possible. Retail, 2s. each.

The Lancet says:—"It is a most valuable form of concentrated food."

The *London Medical Record* says:—"Invaluable for old people; also in convalescence from acute diseases."

A Physician writes:—"I feel I cannot express my gratitude to you sufficiently, as your Beef Jelly is the only thing my niece can retain, and it has certainly kept her alive for the last week."

Benger's Peptonised Chicken Jelly.

In similar glass jars. Retail, 2s. each.

The Lancet says:—"Mr. Benger's Preparations are now so well known that all we need say of the sample before us is—that it is excellent. It has a delicate chicken flavour."

The *Medical Press* says:—"Few modern improvements in pharmacy have done so much as Benger's Preparations to assist the physician in the treatment of the sick."

Benger's Preparations may be obtained through all Retail and Wholesale Houses and Shippers, or of the Manufacturers—

F. B. BENGER & CO., LTD., Otter Works, Manchester.

REPORT OF THE ACADÉMIE DE MÉDECINE OF FRANCE.

Apollinaris

"THE QUEEN OF TABLE WATERS."

"The results of the recent investigations "in Paris and the Report of the Académie "de Médecine of France have placed "Apollinaris Water at the head of all the "waters examined for purity and freedom "from disease germs."

MISTURA CASCARÆ SAGRADÆ COMP.

Prepared from Selected Barks of RHAMNUS PURSHIANA and RHAMNUS FRANGULA, flavoured with AROMATIC SYRUP. *DOSE*— ʒ i. to ʒ iv.

To obtain the best results from the Barks of Rhamnus Purshiana and Frangula it is necessary that they should be collected, not only at the right season of the year but of the proper age, when the bark is neither too young nor too old. Much of that sent to this country consists of bark of all ages, and is consequently not always to be relied upon. In preparing our Mistura Cascaræ Comp. we use only that bark which has arrived at proper maturity, thus ensuring the best results; the menstruum employed being the most suitable for extracting the aperient properties of the bark without causing precipitation when diluted. It is agreeably flavoured with Aromatic Syrup and forms an excellent remedy for Habitual Constipation when continued in doses of ʒ i.; or as an aperient or cathartic, in doses of ʒ ii. to ʒ iv.

"The value of Cascara Sagrada is now very generally recognised. Mackey, Mackey & Co.'s Mistura Cascaræ Sagradæ is evidently prepared from the finest selected material, and we confidently commend this excellent preparation to the notice of the profession."—THE LANCET, Aug. 29th, 1891.

PREPARED ONLY BY

MACKEY, MACKEY & CO., Wholesale Druggists and Manufacturing Chemists.

Please note Change of Address—175, GRANGE ROAD, BERMONDSEY, S.E.

THYROID EXTRACT

(FOR MYXŒDEMA).

A Glycerine Extract of fresh Thyroid Glands, uniform in strength. Prepared from healthy glands, selected by a certain veterinary supervision. A permanent preparation not liable to decomposition. Well suited for internal administration of, which has certain remedy for the hitherto inevitably fatal Myxœdema. Useful in Goitre, Cretinism, &c. Found very successful in the treatment of Psoriasis (see BRIT. MED. JOURNAL, Oct. 28th, 1893, page 933). Exerts a wonderful effect on the nutrition of the skin, and hence deserves wide trial in skin diseases. Promotes the growth of the hair and may prove of use in cases of some kinds.

Price 3s., in 1-oz. stoppered bottles. *Dose*—mx. to ʒj.

THYROIDINE, containing the active principle of the Thyroid Glands of the sheep, 4 grains equal to one-eighth of a fresh gland. Also PILLS and TABLETS, each containing a dose of Thyroidine.

In bottles, 2s. 6d. each.

WILLOWS, FRANCIS & BUTLER, Wholesale & Manufacturing Chemists & Export Druggists.

Address

ON THE

ORIGINS OF SANITATION.

Delivered in the Section of Preventive Medicine at the Congress of the British Institute of Public Health at Hull on Aug. 9th, 1895.

By J. SPOTTISWOODE CAMERON, M.D. EDIN., &c.,

MEDICAL OFFICER OF HEALTH TO THE CITY OF LEEDS; CONSULTING PHYSICIAN TO THE HUDDERSFIELD INFIRMARY, &c.

MR. PRESIDENT AND GENTLEMEN,—In looking back through the long vista of the past one is struck by the importance attached by the first great master in physic to the department of prophecy. To this day the description given by Hippocrates of the man about to die is as vivid and as truthful as when it was first written. But while the foretelling of the probable course of an illness was then, and still remains, amongst the most important powers of the practising physician, the means at his command for arresting in their earlier stages the processes which make for death have enormously increased. There came, indeed, a time, which some of us are even old enough to remember, when pathology ran the risk of being regarded as little else than morbid anatomy and the classification of disease a mere cataloguing of the phenomena immediately preceding death. Indeed, a certain hopelessness, begotten of this mistake, threatened to sap the energies of those engaged in the treatment of the sick. But the natural resilience of science enabled medicine, after a time, to look rather to the causing than to the resulting factors as the basis of classification. Nor was the threatening of fatalism, which too great an attention to induced conditions brought about, entirely without its uses. Though a damaged organ could not be replaced, the processes by which it had arrived at the incurable could be investigated, and their action in another person possibly forestalled; while the study of processes, carried still further back, led not only to a better knowledge of, and better means of dealing with, the causes of disease in the individual, but to a clearer conception of, and greater command over, those etiological factors which had favoured their selection or development.

When Sydenham had, two centuries ago, introduced a rational and hygienic element into treatment, he had also, as it were, pointed in the direction to which, when the hopelessness referred to came upon us, we might look for the prevention of disease itself. A belief therefore in the value of cleanliness, fresh air, and reasonable diet, along with a certain not altogether unhealthy scepticism as to the need in every case of drugs, was not the least important weapon in the armament of the young physician some thirty years ago, and although new drugs have ever found new votaries, and many and valuable means of treatment have been put into our hands, the absolute usefulness of all mere remedial measures is even at the present day looked upon as infinitely little compared with the shielding influence which the physician exercises in placing his patient under the most favourable circumstances for nature to effect her cure. And it is largely this belief in conquering nature by obeying her, lighted up by a certain after-glow of the hopelessness already spoken of, which has caused so much of the energy of the medical profession to be thrown into the preventive service. Nor would it be well entirely to forget that it was in that branch of medicine whose professors wield the knife, and where the results of treatment can most easily be gauged, that the study of the minute living organisms which attack diseased or exposed tissues exercised the mightiest influence in curative treatment; and that the names of Lister and of Koch have marked an epoch not alone in the surgery of wounds, but also in the general history of preventive medicine. While, therefore, the ancient physician was strong chiefly in his acquaintance with, and prophecy as to the probable results of, the processes he saw going on, the modern hygiest attempts to grapple with the remoter causes of those processes themselves, not in the individual alone, but also in the community.

When every rood of land supported its man many of the conditions we have nowadays to face and remedy may have had no existence. The air was fresh; there were no mill chimneys, no foul sewers, no offensive cesspits to make it otherwise; the water was pure: it came unsullied from high untrodden hills or well-filtered from clear springs; the food man ate was plentiful, and worked off by ample exercise; while of business worries he had none. In this Arcadian simplicity possibly he lived; myself I doubt it much. Man has ever been gregarious and ever unwilling to clear away materials for which he has no further use; he has been ever ready rather to get rid of wastes by the natural drainage channels of the country; and bacteria, though unnamed, had their existence all the same.

While, therefore, the country wight had on the whole an immense advantage over the denizen of the town, he was not free from ague on his undrained land; he was subject from time to time to outbreaks of disease from polluted water-supply; nor was he free from poisons generated in the food he had taken means to preserve. Scorbutic complaints were common enough in country districts of England, where fresh food was the exception rather than the rule; but it was after all in towns that the necessity for sanitation was first felt and earliest recognised. When big populations grew up round the graves of their ancestors and drank the water filtered through the subsoil of the churchyard; when huge unventilated factories immured for long hours men, women, and little children, away from light and air; when amongst the masses huddled together the germs of typhus fever or of small-pox ran riot men began to ask: "Were these things needful?" When cholera at length came to our shores and ravaged towns and villages a new era for preventive medicine dawned. Formerly it had been they that were sick, not they that were whole, that sought the physician. But when this Asiatic scourge swooped down upon our towns and villages, carrying away strong men in their strength, people began to repeat and emphasise the question, "Must these things be?" Much learned labour was spent in the study of the disease, but it was etiological inquiries, such as those of Dr. Snow, which pointed to the measures which would do so much, not only to prevent cholera itself, but which would lessen our liability to other and indigenous zymotic diseases. It soon came to be felt that there was a class of maladies, such as relapsing fever, typhus fever, and small-pox, which flourished best only in crowded neighbourhoods; and that there was another class, such as typhoid fever, especially apt to become prevalent where the water-supply was polluted. Nor was it long before it was also seen that such conditions as overcrowding and foul air, polluted drinking water and unwholesome food, were etiological factors in the genesis of diseases other than zymotic, and that not only might undrained fens produce ague, but that damp houses favoured rheumatisms and neuralgias, and generally deteriorated the health of their occupants and lessened their power of resistance to disease. It was noted that accumulations of spent matters about our houses were themselves a cause of illness, and that even where we freed these accumulations from certain of the fouler contaminating substances, conducting the latter by channelled passages direct from the house to the cesspool or the sewer, that these channels themselves became sources of danger. Nor was this danger greatly, if at all, lessened when the idea was suggested of placing traps, in the course of these drains to intercept effluvia generated afar off in the sewer. These traps it was soon found were themselves effluvium producers close at hand, and a system of relieving all pressure in our drains and disconnecting all house wastes from them, as well as of rapidly removing all solid accumulations, came to be regarded as essential to the well-being of a community. Then building by-laws and nuisance inspectors became essential, and every large town provided, either directly or by means of some company, for the supply of water of such purity as might be obtainable.

It had been long acknowledged that certain diseases were wont to spread from man to man, and more particularly from child to child. The ravages of scarlet fever, measles, and small-pox it was found were too little influenced by general sanitary improvements. The last, indeed, was perfectly controlable by means of vaccination. To this process, however, as the disease became less known and less feared, there grew up a not unnatural repugnance on the part of parents, who were unwilling to subject their children to the risk, however slight, of a possible blood poisoning in order to protect them from a disease which their grandfathers had

Digitized by Google

been wont to dread. Then arose the question whether by the separation of the sick from the healthy at their homes where practicable and, where that was not so, in properly equipped hospitals, something might not be done; and it came gradually to be recognised as a duty to the community that notice of the existence of these communicable diseases should be given to the sanitary authority.

It had been found advisable for health purposes that the country should be mapped out into districts, and these placed under the care of properly constituted authorities. These authorities were charged by law with the duty of examining their districts from time to time to seek for certain things which had come to be regarded as nuisances to be dealt with in a sanitary manner. This searching for nuisances was performed in some instances in a somewhat perfunctory manner in a few it was probably not performed at all. While many authorities were anxious in every way they knew to promote the health of those under their care, there were those some of whose members regarded every suggested departure from the old order of things as a medical fad, and opposed to all projected improvements that stolid resistance which the reformer has ever had to fight. Such men when a capable inspector reported on conditions now universally acknowledged to be unhealthy would meet his suggestions with the question, "Has anyone complained?" To such an extent did these obstructionists impede the working of the new sanitary machine it was their office to promote that even more intelligent members of sanitary bodies came to regard the duty of the inspector as one simply of investigating complaints. With the small staff engaged by most authorities the inspector who did no more than this was still often sufficiently actively employed; but the Local Government Board have for many years continued annually to impress upon medical officers of health the desirability of a systematic investigation of some portions of their several districts. Meantime the growth of feeling in favour of the prevention of communicable diseases had induced the health authorities in many large towns to desire and obtain Parliamentary sanction for a system of disease notification. In these towns it was soon felt that, important as the notification of the communicable diseases was in preventing their further spread, scarcely less important was the opportunity such notification afforded of making a complete examination into the sanitary condition of the dwellings where the cases had occurred. Hitherto it had been generally on complaint made that a dwelling was examined. The introduction of a Notification Act enabled the medical officers in such towns with a good grace to press for the examination of every house in which an infectious disease was known to have occurred. Where this was done it was soon found that serious sanitary defects, entirely unknown to their occupants, had often existed in dwellings, and of which, consequently, had an infective disease not broken out nothing would have been heard. These circumstances strengthened the hands of those who were already pressing upon their authorities the desirability of systematically examining their districts. In one town of which I know something every house was examined in this systematic manner. Certain information as to the number of occupants, the number of rooms, and the means of ventilating them, the nature of the water-supply, the kind and efficiency of the drainage arrangements, and the sufficiency and situation of the sanitary conveniences, was collected, along with additional information as to any complaints made by the occupiers about nuisances in the dwelling or its immediate neighbourhood. Without claiming that the whole or even the chief part of the improvement in the health of that town was due to such examination, I would, however, remark that the death-rate, which had averaged for the five years preceding this house-to-house examination 22·3, has averaged during the last five years only 18·6—an improvement of more than 16 per cent. Had the authority insisted on the removal of all sanitary defects so discovered the improvement would probably have been even greater.

Examinations thus made, sometimes in pursuance of a systematic plan, sometimes on account of the outbreak of disease in the near neighbourhood, have again and again revealed the existence of dangers to health of the most appalling kind. To find, for instance, in a row of new houses, in one of which a case of diphtheria has appeared—houses built under modern by-laws and carefully inspected when built; houses with every waste cut off from the sewer, and all the sanitary conveniences outside the dwelling—that a strong-smelling chemical introduced into the sewer penetrated into the house itself in seven out of the ten was startling indeed. This indicates of course that there was a distinct connexion between the air of the sewer and that of the house, and shows the importance of investigating these conditions even in houses as to the sanitary condition of which no complaint has ever been made. Such instances I fear are not uncommon. They go to show that even modern building by-laws, carefully carried out by able inspectors, will not necessarily guarantee a few years later the healthiness of a house.

But what about houses constructed where the by-laws were not modern? In all our large towns there are many houses with wastes not severed from the sewers. In a recent investigation on the outskirts of a large town of some 160 contiguous houses, all more or less recently built and of which nearly two-thirds had all their wastes cut off and the remaining third not, it was found that the smell of a chemical entered the house through the drains in 19 per cent. of the former and in 60 per cent. of the latter. Such instances as these, which could doubtless be multiplied from every large town, seem to point strongly to the importance of a systematic examination of all houses, old and new, house by house, street by street, ward by ward.

It will, I know, be urged that people will object to the examination of houses where no complaint is made. On the contrary, experience shows that they welcome it. Even in the few cases where some hesitation is at first manifested all opposition is got rid of when the object and importance of the visit are properly explained. Practically, therefore, this difficulty has no real existence. It must also be remembered that cottagers are sometimes terrorised by landlords or their agents, and dare not make any complaint, even of the most flagrant nuisance. Such landlords are fortunately not very common, but I have known notice to quit follow a suspected communication with the sanitary authority. Does it not seem a little absurd that necessary sanitary improvements should have to wait till our attention is directed to the house by the notification of some case of infectious disease or the registration of some death altogether preventible? If our sanitary service is to deserve its name must we not everywhere investigate the conditions to be found to be unwholesome, before, and not after, they have led to disaster!

It is now universally admitted that the inhabitants of large towns must be provided with an adequate supply of pure water; that food offered for sale must be strictly and carefully inspected; that our ashpits and our courts the healthy must be frequently and periodically cleansed; and that. And yet must be protected from contact with the infected. ployment in in how many cases do workmen follow their em live in damp or confined workshops? How many per complaint unwholesome dwellings and we hear no word of ? Is till some infectious disease breaks out or some ot it not, I repeat, rather our duty systematically houses, all workshops, and to ascertain beforehan the conditions there present are those which destroy the health of those they are intended and protect?

ON HICCOUGH.

By JOHN O. LEONHARDT, M.D.

I HAVE been much interested of late in the articles on this subject appearing in THE LANCET and medical periodicals. Medical literature seems to be larly deficient on the subject of hiccough, which for turies has been, and still is, one of a number of harlequins. Nothing is more common, trivial, and treat than a mild attack of singultus, and yet, wh appears in its grand types, nothing is more distressing patient and harassing to the physician than this conv affection of the diaphragm.

Upon referring to my case book I find that on Sept. 1878, I was called to see a man who had hiccoughed santly for two days and nights. I found the patient large, plethoric person aged sixty; his pulse was rapi small, the skin hot and dry, and he suffered from grea lessness with busy delirium, together with coughing hiccoughing with every inspiration. It was impossi

Digitized by Google

determine with any degree of accuracy the condition of the lungs and heart owing to the agitation of the patient and the great commotion within the chest. The patient appeared to be in a very critical condition. I prescribed an active hydragogue and half a grain of sulphate of morphia by the mouth. The cathartic acted in a short time and the patient fell asleep, but the hiccough continued. I then began to use antispasmodics and sedatives, and tried counter-irritation and everything that might be expected to quiet the spasm for about a week, but without the least effect. Death seemed inevitable. Just "for the sake of doing something" I then ordered twenty drops every half hour of a mixture containing equal parts of acetic and sulphuric acids. An unexpected and decided improvement took place, and my patient became convalescent within twenty-four hours. He had hiccoughed constantly, day and night, awake or asleep, under the influence of hypnotics or not, for eight days. He removed farther west, and recently I learned that about ten years after the attack of 1878 he died from a similar attack.

My attention having been attracted by numerous communications on this subject occurring in many medical as well as lay journals, I have looked over the literature of hiccough, or, rather, as much of it as I have in my library. Thinking that the result of my explorations may at least interest, if not benefit, some fellow practitioner, I submit a few observations that seemed to me both interesting and instructive. Citations are appended in order that those who desire to refer to any particular case may easily do so.

1.—A male negro, aged forty, was admitted to the Hospital Hôtel Dieu for chills, dyspnœa, and hiccough. He would hiccough constantly for five or six minutes and then enjoy a short period of rest. Bleeding, cupping the epigastrium, and hydrocyanic acid, used internally, were resorted to, but with no effect. After twelve days he recovered while taking laudanum and ammonia.

2.—Dupuytren cured two violent and obstinate cases by use of the actual cautery applied over the xiphoid cartilage.

3.—De Meza of Helsinfors reports a case in a male aged sixty, corpulent, phlethoric, and addicted to "bacchanalian pleasures," who, having suffered for nine days from gastric disturbance, took an emetic, and immediately a violent and unceasing hiccough ensued. Asafœtida, camphor, musk, venesection, &c., were all tried in vain. After lasting for three days the spasms ceased under a blister applied to the abdomen.

4.—Dr. Barlow reports a case in a male aged sixty-one, suffering from migratory rheumatism. When he moved his shoulders it would bring on a paroxysm of hiccough, and that even when the rheumatism had settled in his ankles.

5.—Mindiere, in the *Revue Medicale*, directs attention to the influence of malaria on the viscera and its expression in severe hiccough. In support of this a case is reported of a countryman who, recovering from an attack of ague, was seized with a violent hiccough which, in spite of opiates, blisters, and antispasmodics, persisted for nine days, when it disappeared under enemata of quinine.

6.—Case of a young lady troubled with chronic gastritis, who hiccoughed for an hour daily, which yielded only to galvanism on the forty-second day. Dr. Jones of New Orleans has found that faradaism is best in asthenic and galvanism in sthenic cases.

7.—Dr. Boyer reported three cases, in which everything was tried without good effect, where the hiccough yielded to forcible compression of the epigastrium continued for twenty-four hours at a time.

8.—M. Latour reports a case in a male aged forty-six years, very nervous and of weak constitution, who suffered severely for three hours and was cured by inhaling chloroform.

9.—Dr. Schneider of Berlin reports having cured many cases of violent and persistent hiccough by giving dilute sulphuric acid. In this treatment Dr. Duncan of Edinburgh and Dr. Jacobson of Berlin concur.

10.—Dr. Danet, in a severe case following great mental disturbance and associated with headache and vomiting, after trying a great number of antispasmodics in vain, mastered the hiccough with a pill containing three-quarters of a grain of valerianate of zinc and a small quantity of belladonna.

11.—Leon Boyer reported three cases: one a female aged eighteen suffering from suppressed menses; the second a male aged twenty-five troubled with "oppression"; and a third of which no particulars are given. After using many remedies and methods all three were cured by firm compression of the epigastrium. This treatment was suggested to him by Professor Rostan, who in turn got it from Bordeu, who long ago recommended a tight bandage around the epigastrium.

12.—The value of morphia injected hypodermically is admirably set forth by Dr. Edward T. Wilson.

13.—Dr. Constable treats of hiccough as a complication of pneumitis, and recommends the subcutaneous injection of morphia.

14.—Dr. Jauariz mentions the case of a Spanish physician who, having recovered from an attack of gastric fever, was seized with an obstinate hiccough. After sixty hours of suffering—during which he took emetics, revulsives, antispasmodics, &c.—he besought his wife to give him a drink of linseed tea. She gave him by mistake an infusion of mustard. His hiccough immediately disappeared. This modification of the treatment of Rhazes proved effective in his hands in the case of a lady afflicted in the same manner, every other treatment having been unsuccessful for twenty days.

15.—Dr. Rose relates that Widal cured a nineteen-day old case with twelve grains of quinine daily for three days, and speaks of another cure in which valerianate of zinc and belladonna were used, and still another cured with Vichy water and gentian. He recommends the use of ether spray to the neck and epigastrium.

16.—Dr. Ringer's case of hiccough in an Indian trooper, the victim of syphilis in the rupial stage, resisting all kinds of hypnotics and antispasmodics, also counter-irritation and calomel. He finally obtained a good result after thirteen days by giving large doses of potassium iodide, applying a blister over the phrenic nerve and giving iced water to drink.

17.—Dr. Fritsch reports a case of hiccough in a married female suffering from "excoriation at the portio vaginalis uteri, with a cervical catarrh," which ceased only when the genital affection was cured after a treatment lasting three months.

18.—Dr. Favier reports a case that lasted three weeks, and which abated under tourniquet pressure over the epigastrium, morphia, the actual cautery, musk, quinine, chloral, &c., being of no use.

19.—Belot found compression of the phrenic nerve on a level with the hyoid bone very effective in hiccough accompanying yellow fever.

20.—Dr. Ortille cites a case of hiccough following cerebral embolism, in which a multitude of remedies had been tried, and which yielded to half a grain of pilocarpine hypodermically. In this case the hiccough persisted during sleep and disappeared during the profuse perspiration and salivation induced by the drug.

21.—Dr. Barre reports a remarkably persistent case in a male aged forty-five, suffering intense grief. Everything imaginable was done without success. At the end of two years, and for the mere sake of doing something, an œsophageal probang was passed. This caused a syncopal attack, but cured the hiccough. Carcassonne employed the same measure.

22.—Dr. Ortille relates a case of hiccough in a female aged fifty-six which had continued for seven months. In this case a decoction of four grammes of jaborandi leaves and stalk, to be taken in two doses fifteen minutes apart, was prescribed. It cured the patient in two hours. No reason is given why the crude drug was preferred in this instance to the active principle generally employed.

23.—Dr. Warren of Danville, Kentucky, recommends to "hold the breath as long as possible; the trisplanchnic nerve is held in abeyance until the pneumogastric, which is off its guard, can get back to its post." This method is in line with Cruveilhier's, which consisted in pouring water into the patient's mouth until he was about to suffocate. It may also "explain" why forcible expiration, cold douches, sudden alarm, sneezing, straining with the glottis closed, and Carcassonne's forcible flexion of the head upon the chest for five or ten minutes at a time, are all occasionally successful.

24.—Dr. Rihl reports two cases of hiccough, one in a male aged thirty-five, following an attack of syncope; it continued for many months in spite of the use of "the web of the black spider," and ultimately wore itself out; the other in a female aged forty, who for twenty years had been afflicted with some obscure form of spinal disease. Among the remedies used in the second case may be named grindelia robusta, turpentine, chlorinated soda, Hoffman's anodyne, cypripedium, bicarbonate of soda, and oil of amber. She hiccoughed fourteen weeks out of seventeen, and no result of the case is given.

25.—Dr. Foote relates several remarkable cases in a very

Digitized by Google

lucid and instructive manner. One, a male aged fifteen, dyspeptic, after having undergone many kinds of treatment was cured with a pill containing one grain of iodoform, one-third of a grain of cannabis indica, and five grains of extract of conium, at the end of twenty-six weeks of affliction. In another case a female aged twenty-two, after seven months of hiccoughing, was cured by electricity. A third case, that of a girl in which the hiccough was induced by severe fright, proved fatal.

26.—"R. H. P." cured a number of cases by the inhalation of tobacco smoke.

27.—At a meeting of the St. Louis Medical Society in the winter of 1882 a case of hiccough was exhibited that had been active for twelve years, and still proved refractory to all treatment.

28.—Mr. Lea mentions the case of a man who was tormented with hiccough with every irritation or the least exertion. Ten-drop doses of tincture of opium afforded most relief. The necropsy revealed cancer of the stomach.

29.—Dr. Bernstein reports an interesting case with necropsy. A male aged forty-four was admitted to the Borough Hospital, Birkenhead, for hiccough and pain in the lower part of the back and loins. He was subjected to many remedies without permanent relief. Croton oil did more good than any other drug. At the necropsy nothing appeared to explain the hiccough unless it was that a caseous deposit at the apex of each lung might have impinged on the vagus or phrenic nerves.

30.—Dr. Kingsbury narrates a case of hiccough that persisted during sleep in a male aged fifty. It followed a vertiginous attack. Purging, blisters to the abdomen, potassium bromide, acetic acid, chloroform, hydrocyanic acid, and pressure over the phrenic nerves were all tried, but to no purpose. He was cured after twelve days with chloral hydrate.

31.—Dr. Pipino of St. Louis, Mo., reported a distressing case of hiccough in a male aged seventy-three in which every ordinary remedy failed and which finally was cured by the subcutaneous injection of three centigrammes of pilocarpine.

32.—Dr. Pagenstecher, in a bad case of obstinate hiccough, having canvassed the whole range of probable medicine, found a decoction of jaborandi leaves curative on the sixth day. Noble and Stiller warmly recommend this treatment.

33.—Dr. Ruhdorfer mentions a case in a female in which sedatives, emetics, irritants, cathartics, cupping, &c. were tried for three months. A successful result followed the hypodermic injection of three centigrammes of pilocarpine in a gramme of water. The hiccough stopped as if by magic.

34.—Dr. Ramos of Brazil recommended refrigeration of the lobe of the ear, slight cold being sufficient. Even the application of cold water proved curative in hiccough regardless of its cause.

35.—Dr. Churton describes an intermittent form of hiccough in a neurotic and dyspeptic female aged twenty-five. The first attack, lasting ten days, ceased after the subcutaneous injection of morphia and inhalation of chloroform. After one week it began again and continued eleven days, when it was stopped in ten minutes with a hypodermic injection of one-fourth of a grain of pilocarpine. In two subsequent attacks pilocarpine acted admirably, but in a fourth it proved useless, but scutellaria in drachm doses proved curative. This last drug acted well in another case.

36.—Dr. Bonavia reports a case in an adult male that followed an attack of intermittent fever, and it is said that everything proved futile except drachm doses of fluid extract of ergot. Quinine does not appear to have been given a trial.

37.—Dr. Dresch of Foix, France, speaks of a method, not original with him, but very effective, in which the patient's external auditory canals are firmly closed with his fingers and he is caused to take a few sips of fluid from a cup held by another person.

38.—Dr. Luke recommends a teaspoonful of pulverised sugar given with an equal volume of vinegar at one dose.

39.—Dr. Leloir reports a case in a female aged twelve. After trying everything for a year he finally practised compression of the phrenic nerve between the two sterno-clavicular attachments of the sterno-mastoid muscles for three minutes at a time with curative effect.

40. Dr. Smart, in a case of hiccough occurring in an adult male suffering from chronic alcoholism, after trying for four or five weeks to control the spasm, used inhalations of chloroform with success.

41.—Mr. Slevin reports a case of hiccough that continued during sleep in a male aged seventy-eight who had recovered from an attack of gastric catarrh. "Every remedy of any repute" was tried. It ceased upon the inhalation of snuff, which caused sneezing. It had been constant for twelve days.

In the foregoing observations it will appear that pilocarpine, epigastric compression, morphia, and chloroform are the mainstays of several able practitioners in the treatment of this disorder. It will also be seen that hiccough in aged males is of shorter duration, as a rule, than in young females. Among the causes are found any irritation of the phrenic nerves, whether reflex, central, or peripheral. Its occurrence is common in the advanced stages of fatal diseases of all kinds: in uræmia, cholera, dysentery, gangrene, hæmorrhage, low fevers, and adynamic states generally; in apoplexy, hydrocephalus, meningitis, embolism, acute gastritis, cancer of the stomach, pericarditis, aneurysm, pneumonia, intestinal obstructions, strangulated hernia, and the passing of renal and hepatic calculi; in mediastinal pleuritis, fracture of the ribs, malaria, gouty inflammation of serous membranes near the diaphragm, spasmodic stricture of the œsophagus, affections of the larynx or pharynx, and enlargements along the sides of the thyroid or in the course of the phrenic nerves; in many diseased conditions of the liver, spleen, pancreas, ovaries, uterus, prostate, &c.; even from ingestion of irritating substances, solid or fluid, so common in those addicted to rapid eating, gourmandising, drunkenness, &c.; excessive crying or laughter is sufficient to cause hiccough in children and those of unstable nervous systems.

While the above excerpts will doubtless puzzle the "symptom doctor," the pathologist and real clinician will have no difficulty in distinguishing the real from the apparent. It certainly appears plainly that hiccough is not a disease *per se*, but rather a neurotic equivalent occurring in many different diseases. While obscure but trivial nervous conditions may coexist with a paroxysm of singultus which is usually readily amenable to simple measures often of a psychical character entirely, hiccough may be of so threatening and obstinate a nature that the resources of the ablest may be of no avail. It is in cases of the latter kind that a primary morbosity, if sought for, can, I believe, usually be found, and of which the diaphragmatic convulsions, though all-absorbing, are really but like the white crests of waves that, however conspicuous, are distinctly dependent upon the energy of sun and wind and water. Hiccough is not a disease; it belongs to a class of imposing symptoms of which neurasthenia, dropsy, jaundice, fever, &c. are examples. The physician who permits himself to be deceived by the boisterous qualities of any disease shadow, which he assails regardless of the character of the real pathological substance that casts it, lacks medical acumen and exposes his patient to much unnecessary suffering and possibly danger.

NOTES ON THE BACTERIOLOGICAL EXAMINATION OF THE THROAT IN SOME FEVERS.

BY J. O. SYMES, M.B., L.R.C.P. LOND., M.R.C.S. ENG., D.P.H., &c.,

ASSISTANT MEDICAL OFFICER, LONDON FEVER HOSPITAL.

DURING the past twelve months a bacteriological examination of the throat has been made in all cases admitted to this hospital in which there were signs of exudation on the fauces. Cultivations have also been made from time to time from throats presenting no abnormal appearances. As a rule, the cultures were taken upon admission, but some after a stay of from two to eight weeks in the wards. A sterilised swab of cotton-wool upon a rod was passed lightly over the fauces and tubes of blood serum inoculated from this. The publication of a brief summary of the notes of the first 100 cases so examined may be of interest at the present time, in view of the increased attention paid to the bacteriology of diphtheria. All the cases were under the care of Dr. J. W. Washbourn, and it was at his suggestion that the examinations were made.

SCARLET FEVER.

Bacteriological examinations were made of exudation from the throats of 68 patients suffering from scarlet fever; 52 were made on the day of admission, 8 during the first seven days, and 8 at periods varying from the third to the eighth week. Of these cultivations 14 showed pure streptococci, 25 streptococci and cocci in groups, 2 cocci in groups, 1 cocci and the long variety of diphtheria bacillus, 9 cocci and the short variety of diphtheria bacillus, 14 cocci and other forms of bacilli, and 3 showed various forms of bacilli only. The bacillus most frequently found was a short, stout variety with a central non-staining portion. It was arranged in chains or groups, and liquefied serum in from three to six days.

Case in which the long variety of diphtheria bacillus was found.—A child aged eighteen months had a mild attack of scarlet fever. During the seventh week there was rhinorrhœa, but no membrane could be seen in the nasal cavities. A culture taken during the eighth week showed greyish, raised, and liquefying colonies, which proved microscopically to consist of cocci and diphtheria bacilli of the long and short varieties. A pure culture of the long variety proved virulent to guinea-pigs. Seventeen days later the discharge ceased and cultivations showed cocci only. The temperature did not rise above the normal; there was a slight trace of albumin in the urine. No paralysis followed, and the child made an uninterrupted recovery.

Nine Cases in which the "Short Variety of Diphtheria Bacillus" was found.

CASE 1.—Much exudation on fauces. Cultivation taken on admission showed cocci and short diphtheria bacilli, which persisted until the seventh week. The throat cleaned quickly, but fresh exudation appeared on the tenth day after admission.

CASE 2.—Culture taken on admission showed in twenty-four hours raised white colonies of cocci and the short variety of diphtheria bacillus. There was much exudation on the palate and fauces, which cleared to return again on the thirteenth day. Bacilli were present up to the sixth week. Slight nephritis was present.

CASE 3.—Exudation on fauces. Culture taken on admission showed raised white colonies in forty-eight hours, streptococci and short variety of diphtheria bacilli. The patient subsequently developed paresis and anæsthesia of the palate, albuminuria, and loss of knee-jerks. Cocci only on twenty-second day.

CASE 4.—Exudation on tonsils and palate. Culture taken on admission in eighteen hours showed liquefying and white raised colonies of large oval cocci, streptococci, and short variety of diphtheria bacilli. Six weeks later cultivation from throat showed cocci only. There was slight nephritis.

CASE 5.—Rhinorrhœa three weeks after admission. The nasal cavities were coated with white fibrinous exudation. Culture in twenty-four hours showed raised white colonies of oval cocci and short diphtheria bacilli. No paresis or albuminuria followed.

CASE 6.—Culture from fauces, which showed no sign of exudation, was taken on admission, and showed fine, raised, white colonies in twenty-four hours, cocci and short variety of diphtheria bacilli. Seventeen days later a second cultivation from the throat showed cocci only. At no period of the case was there any abnormal appearance of the fauces, and recovery from scarlet fever was uninterrupted.

CASES 7, 8, and 9.—On admission the fauces showed no exudation, nor did any throat trouble subsequently develop. Cultures taken on admission showed in twenty-four hours colonies of streptococci and of short diphtheria bacilli. In Case 8 short diphtheria bacilli were still present three weeks after the date of admission.

DIPHTHERIA.

Cultures were made from the throats of 18 persons sent to the hospital certified as suffering from diphtheria. The cultivations were taken on admission and examined after periods of incubation ranging from sixteen to forty hours. In 10 out of the 18 cases long diphtheria bacilli were found.

CASE 1.—Raised, round, white colonies were present in twenty-four hours of the long and short varieties of diphtheria bacillus. The short bacilli were demonstrated as present in the throat twelve weeks after admission. A pure culture was not virulent to guinea-pigs. The patient was treated with antitoxin. No paresis occurred.

CASE 2.—Cocci in groups and long diphtheria bacilli. Bacilli present until sixth week. No paresis. Antitoxin used.

CASE 3.—Cocci in groups and long diphtheria bacilli, which were absent on thirteenth day. Patient had tachycardia of several days' duration. No paresis of palate or other muscles.

CASE 4.—Streptococci and long diphtheria bacilli. Bacilli had disappeared by twentieth day. Complete loss of knee-jerks.

CASE 5.—Long diphtheria bacilli, which persisted up to thirty-first day. Anæsthesia and paresis of palate. Treated with antitoxin.

CASE 6.—Liquefying colonies of cocci, long variety of diphtheria bacilli. Died seven days after admission from cardiac failure. Treated with antitoxin.

CASE 7.—Long and short diphtheria bacilli. Culture on twenty-third day showed cocci only. Paresis of palate followed. Antitoxin given.

CASE 8.—Long variety of diphtheria bacillus. Streptococci and cocci in groups. Five weeks after admission cocci only. Paresis of palate. Antitoxin used.

CASE 9.—Long variety of diphtheria bacillus and streptococci. No paralysis followed attack. Antitoxin used.

CASE 10.—Long variety of diphtheria bacillus and large oval cocci. Culture taken nine days after admission showed cocci only. On sixteenth day there were fresh membrane on fauces, rise of temperature, and some albuminuria. Cultures showed long diphtheria bacilli, which were again absent from cultures taken during fourth week. No paresis. Antitoxin given on admission and repeated on sixteenth day.

Eight Cases certified as Diphtheria in which the Klebs-Löffler Bacillus was not found.

CASE 1.—Much exudation on palate and fauces. Cultures showed torulæ, streptococci, and cocci in groups. Patient developed a well-marked attack of enteric fever, and at no time was there evidence of diphtheria.

CASE 2.—Exudation on tonsils. Culture showed colonies of streptococci and of staphylococci pyogenes aurei. This proved to be a case of scarlet fever and desquamated freely.

CASE 3.—Profuse acrid nasal discharge containing streptococci and streptobacilli. In a subsequent cultivation streptococci, staphylococci pyogenes aurei, and short liquefying bacilli were present. A case of scarlet fever which desquamated. Nine weeks after admission pus from cervical abscess showed streptococci.

The remaining 5 cases were regarded as cases of tonsillitis. Cultures yielded the following results.

CASE 4.—Streptococci and cocci in groups.

CASE 5.—Streptococci. Sloughing tonsils and apex pneumonia.

CASE 6.—Streptococci, cocci in groups, and short, stout

Digitized by Google

oblong bacilli. Culture taken on third day showed cocci only.

CASE 7.—Cocci in groups.

CASE 8.—Streptococci and large oval cocci.

In none of the eight cases mentioned above was loss of knee-jerk or any symptom of paralysis observed.

RUBEOLA.

Cultivations were taken from the throats of 14 cases of rubeola. Colonies of short, stout bacilli, sometimes in chains, which liquefied serum in forty-eight hours were found in 3 cases. Two of these had exudation upon the fauces. Similiar bacilli, together with cocci in chains and groups, were found in 4, streptococci alone in 1, and streptococci and staphylococci in 3 cases. Cultivations from the three remaining cases showed colonies of cocci, together with the "short variety of diphtheria bacillus."

CASE 1.—Forty hours culture showed large, white, raised colonies of cocci and short diphtheria bacilli. Cultivation taken three days after admission gave the same result. On the thirteenth day after admission cocci only were found. There was a patch of whitish exudation on the palate that persisted for nine days. Slight trace of albumin in urine. A pure cultivation was not virulent to guinea-pigs.

CASE 2.—Forty hours culture showed circular white colonies of cocci and short diphtheria bacilli, which were present until the thirteenth day after admission. The fauces were slightly coated with whitish exudation. Faint trace of albumin in urine.

CASE 3.—Forty hours culture showed white raised and transparent raised colonies of short diphtheria bacilli and of streptococci. The bacilli were present in a culture taken on the ninth day. There was no exudation on the fauces.

There was no evidence of diphtheria in the further history of any of these cases.

Remarks.—The necessity for a bacteriological examination in all supposed cases of diphtheria is sufficiently obvious. It is worthy of notice that in none of the eighteen cases admitted certified as suffering from diphtheria was "the short variety of diphtheria bacillus" found. Of the nine scarlet fever and three German measles cases in which this bacillus was detected only one (Case 3, scarlet fever) presented clinically the features of diphtheria. Dr. Washbourn tested pure cultures of the "short variety of diphtheria bacillus," obtained from some of the above-mentioned cases, but none were virulent to guinea-pigs.

Southwick-street, W.

PNEUMONIA AFTER INFLUENZA.

BY GUTHRIE RANKIN, M.D. GLASG., F.R.C.P. EDIN.,
LATE MEDICAL OFFICER, WARWICK DISPENSARY AND COTTAGE HOSPITAL.

IN the outbreak of influenza which developed so suddenly over this country in February last, and which happily has now subsided, pneumonia was the complication most to be dreaded and was the immediate cause of death in a large proportion of cases. In previous epidemics pneumonia has always been a common sequela, but in the present instance the examples which have come under my observation have presented certain characteristics strikingly different from the ordinary type of the disease. This year's epidemic first broke out in this neighbourhood in an institution which comprises a resident population of close upon 150, and the cases to which the present notes refer, though not essentially different from others met with in outside practice, were brought under notice with special prominence because of the concurrence under one roof and at one time of several bearing the same characteristics and exhibiting the same departures from the ordinary standard. Very few of the 150 escaped the attentions of the disease: many were so slightly ill as to require little care; others experienced an ordinary attack of the malady, which incapacitated them for three or four days, but which left them at the end of that time practically well; while a few had to contend with it in a more pronounced form, and of this latter number five suffered from pneumonia. The hygienic arrangements of the institution are well devised, carefully looked after, and the average health of the inmates leaves nothing to be desired. Of the whole number attacked by influenza, only seventeen were acutely ill, and, except the cases now under consideration, they all recovered completely and within a comparatively short time. The matron, who was the first victim of pneumonia, died from cardiac failure on the eighth day of her illness. Her case proved fortunately to be the only fatal one, and while the leading features of her attack were the same as in all the others her chances of recovery were lessened by the previous existence of a complicated form of heart mischief. Of the other four cases one was mild and abated on the fourth day, another resolved by lysis, and the remaining two by crisis, each on the eighth day of the illness. It should perhaps be noted that the case which resolved by lysis was the son of parents who were first cousins and in whose family history there was a pronounced phthisical taint. The symptoms of all five cases were strikingly similar, and a short description of one will best serve to call attention to the unusual features of the whole series.

A lad aged fifteen, with a fair physique but with a neurotic diathesis, was seized with influenza in a sharp but ordinary form. From this he emerged like his neighbours, but on the third day from the date of recovery from his influenzal attack he complained of not feeling so well. His temperature in the morning was 100° F., but there was then nothing to suggest the advent of inflammatory mischief anywhere. In the afternoon the temperature rose rapidly to 105·4°, the pulse was 120, and the respiration 44. There had been no rigor, he had no cough, no pain, and he complained of nothing but shortness of breath and thirst. Next morning the temperature was 100·4°, the pulse 100, and the respiration 40. He still had no pain and the cough was trifling, but he had constant nausea and occasional attacks of active sickness. Later in the day his temperature gradually rose to 103·4°, and in the evening it reached 105·2°. Under the influence of quinine and cold-packs it receded, but at 10 o'clock the following morning it again reached 104·6°, the pulse being 100 and the respiration 38. There was no cough, but that morning he had twice expectorated some frothy mucus of a bright red colour; the nausea continued. He complained of wandering pains over his right side, which he mostly referred to the axillary region above the level of normal liver dulness, but physical examination failed to reveal any explanation. For the next three days his temperature did not exceed 104·4° and was readily brought down to between 100° and 102° by cold sponging. At 2 P.M. on the eighth day it registered 103·6°, and at 10 P.M. it had fallen to 99·2° from which there was no subsequent rise. During those three days his pulse varied from 80 to 100, but did not exceed 104; his respiration had never been less than 50, and frequently had numbered 65. The amount of cough was so small as hardly to deserve mention, and there was no return of the red sputum; indeed, there was no expectoration of any kind. The physical signs remained indefinite, but some comparative dulness developed over the right lower lobe, and there was bronchial breathing with slight increase of vocal fremitus in this region. After the crisis was over, on the eighth day, the physical signs rapidly vanished, without expectoration or cough or pain, and with no decided crepitatio redux, till on the eleventh or twelfth day the patient was perfectly sound and only required time and care to restore his tone and re-establish his usual vigour.

In none of those five cases did a herpes develop, except in that of the lady matron, who died, and this is significant because from time immemorial the occurrence of herpes in an ordinary case of pneumonia has been looked upon as a favourable indication. The unusual features of this short history are the absence of cough, the exceeding scantiness of expectoration, the frequency of respiration, the comparative slowness of pulse, even under the pressure of high temperatures, the entire absence in the early stages of physical signs, their very imperfect development later, and their speedy disappearance without notable crepitatio redux after the arrival of the crisis. None the less, the duration of the illness, its mode of termination, the pulse-respiratory ratio, the sudden initial high temperature, &c. are strongly characteristic of the common, everyday pneumonia. But, whatever the modifying effect of the influenza poison may have been, we are driven to ask ourselves whether it is probable, or even possible, that the local condition could be the sole cause of the grave constitutional disturbance, or whether the hyperæmia and slight hepatisation of the lung would not better fit into the theory of its being a consequential rather than an etiological incident in the history of the disease; whether, in short, such cases are not a strong argument in favour of the specificity of pneumonia. In the last edition of "Quain's Dictionary of Medicine"

Digitized by Google

Dr. T. Henry Green tersely states: "The old view that pneumonia is a simple local inflammation accompanied by a symptomatic pyrexia would appear to be no longer tenable; and although a complete pathology of the disease must await further investigations the present position of our knowledge makes it in the highest degree probable that it is a *general infective disease* closely allied to the acute specific fevers, of which the lung inflammation is the characteristic local lesion. What is known of the etiology of the disease, the absence of any constant relation between the local inflammation and the intensity of the fever, the "typical" course of the fever, the fact that the disease is incapable of being produced by mechanical or chemical injuries of the lung; and, lastly, the discovery of peculiar micro-organisms all tend to support this view of its pathology."

Influenza is widely recognised as one of the specific diseases which, in all probability, owes its existence in great measure to microbic action. The toxines secreted by its microbes are known to possess a special affinity for the nervous system. This is evidenced by the prostration, inertia, neurasthenia, hypochondriasis, and sometimes even melancholia which abide in greater or less degree as a legacy of the most ordinary attack. Pneumonia behaves in many respects like the other acute specific fevers and has been demonstrated to possess micro-organisms which are capable, when inoculated into certain animals under favourable circumstances, of setting up, if not the true disease, at least a septicæmia of which a consolidated lung is the striking characteristic. Many of the prominent features of the everyday inflamed lung depend upon interference, from whatever cause, with the normal stability of the lung nerve-supply.

In the pneumonias, such as those above related, met with as complications of influenza we have to deal with either: (1) the ordinary disease, more or less modified by the previous systemic disturbance of the influenzal attack and occurring as an accidental sequela; or (2) an entirely different disease, bearing close analogies to the classical disorder, but owning a different cause and entirely dependent for its manifestations on the pre-existence of influenza. If the former hypothesis be the true one, and it seems the more likely, then true pneumonia is capable of modifications in its symptomatology, and, assuming that the pneumococcus is a constant concomitant of the disease, whether causative or otherwise, an explanation of these anomalies may be suggested by the possible want of perfect concurrence of action of one class of microbe with another, either in the respiratory tract, where the micro-organisms of both diseases are abundantly found, or in the blood itself; or else by the counteracting influence of the one set of resulting toxines with the other, producing, both directly and reflexly, results different from those to be expected from the unfettered action of either. If, on the other hand, the latter alternative be the right description of the condition, the new pneumonia which finds its parentage in influenza bears such a close resemblance to its better-known prototype that in all probability the pathological mechanism which causes the one is very closely allied to that which is responsible for the other. Further, if the predilection of both toxæmic secretions is the nerve centres, their disturbing effect in the neighbourhood of the fourth ventricle would go far to account for all the symptoms; not only such as are recognised as normal in an ordinary pneumonia, but also those which, however different from the common type, unmistakably proclaim that the usual course of an attack of influenza has become complicated by the occurrence of an inflamed lung.

Warwick.

APPENDICITIS AND RHEUMATISM.

BY G. A. SUTHERLAND, M.D. EDIN., M.R.C.P. LOND.,
PHYSICIAN TO THE NORTH LONDON CONSUMPTION HOSPITAL AND TO OUT-PATIENTS PADDINGTON-GREEN CHILDREN'S HOSPITAL.

IN the numerous papers and monographs on the subject of appendicitis which have appeared within recent years one point does not seem to have attracted much notice—namely, the association of appendicitis with constitutional disease. By this I do not mean the occurrence of such lesions as ulceration of the appendix in typhoid fever or tuberculosis, but the question whether the tissues of the appendix can be so acted upon by a poison circulating in the blood as to become acutely or chronically inflamed. In this paper I shall refer to some points in the anatomy, physiology, and pathology of the appendix which seem to render such a view probable, and then discuss more particularly the association which I have found clinically to be most frequent—namely, that of appendicitis and rheumatism.

Special attention has been paid recently to the large amount of lymphoid or adenoid tissue which is present in the substance of the vermiform appendix. This has been noted by Mr. Bland Sutton, Dr. Kelynack, Dr. Hingston Fox, Mr. Mayo Robson, and Dr. R. J. A. Berry. Mr. Bland Sutton[1] speaks of the appendix as an abdominal tonsil, since lymphoid tissue is the chief structure in both appendix and tonsil, and there are marked similarities in the inflammatory and suppurative attacks to which these organs are subject. Dr. Berry[2] has made a careful investigation into the comparative histology of the appendix and cæcum, and has found that at the apex of the cæcum a mass of lymphoid tissue is usually present. He says: "In some classes the cæcum is composed almost entirely of lymphoid tissue, and in others these lymphoid elements are contained in an offshoot of the cæcum—the vermiform appendix. This differentiation of the lymphoid tissue into a special organ becomes more marked with the ascent in the vertebrate scale." As the liability of lymphoid tissue to inflammation is well known, these anatomical facts may throw some light on the pathology of appendicitis, and their bearing on this subject will be referred to later.

The vermiform appendix is usually regarded as a functionless organ (Treves, Talamon, Bland Sutton, &c.), but its richness in lymphoid tissue suggests at least one possible use—namely, the production of leucocytes or lymphocytes. In other parts of the alimentary canal the importance of adenoid tissue has now been fully recognised, and the action of the lymphocytes produced in it has been explained. Dr. Sims Woodhead says: "It has now been very generally accepted that passing to and from the patches of lymphoid tissue in the walls of the alimentary canal, into and out of the canal itself, are numerous leucocytes, amœboid cells, or lymphoid corpuscles, as they are sometimes called. Further, it has been demonstrated that these small cells have the power of taking up foreign particles and of digesting them, or of so transforming them that unless they consist of particles of pigment they disappear; amongst these foreign bodies may be numbered bacteria of various kinds."[3] It would naturally be expected, then, that these functions ascribed by Dr. Woodhead to the diffused lymphoid patches of the alimentary canal would characterise also the large amount of this tissue present in the appendix, and such a view is strongly supported by the results of a recent experimental research made by Dr. R. J. A. Berry.[4] He describes the function of the appendix as twofold: (1) leucocyte-producing, and (2) secretory; and as regards the leucocytes he considers that they are of use both in the destruction of micro-organisms and in the absorption of proteids. Dr. Armand Ruffer, in describing the action of the lymphocytes (or "microphages") of the lymphoid tissue in the alimentary canal in absorbing micro-organisms and foreign matter, states that "the patch near the rabbit's ileo-cæcal valve and the vermiform appendix are the structures in which these processes are most marked."[5] From the situation of the appendix at the first part of the large intestine it is manifest that these functions will be of great service. The cæcum is apt to become loaded with fæcal matter in which bacteria of all kinds flourish, and were there not some such protective power in the form of lymphocytes as described above decomposition would go on unchecked, and symptoms of auto-intoxication would probably be extremely common.

The pathology of appendicitis cannot be said to be clearly understood. By most writers the disease is regarded as a purely local one dependent on local causes. The presence of catarrh, or a concretion, or cystic dilatation, or a kink or twist of the appendix is held to be a sufficient explanation of the morbid phenomena. The list of those local causes is already a large one and is still being added to, and yet numerous cases remain in which no cause has been ascertained. Further, it is a question whether many of these so-called causes are not really the results of inflammation in the appendix and the surrounding structures. Talamon admits that in simple inflammatory attacks the essential

Digitized by Google

lesion is a parietal one, as has been proved by the early operations of American surgeons. He says: "The appendix becomes increased in size, and appears dilated, turgescent, and erect, being about the size of the little or index finger; its walls are thickened, and its cavity is enlarged and filled with viscid or semi-purulent mucus."[6] Such a condition, however, is by no means limited to simple inflammatory attacks. Mr. Arbuthnot Lane has described a case of acute general suppurative peritonitis secondary to appendicitis for which no local cause, such as those mentioned above, was found. He says: "The appendix was as large as one's thumb and intensely livid. After it was removed it was carefully examined, and although covered with lymph it was perfectly intact and had no smell whatever. On dividing the appendix longitudinally the muscular and mucous coats were much hypertrophied, and the whole thickness of the bowel was enormously increased by the very acute inflammatory process. There was nothing found in its interior beyond a little fluid faces, and there was no evidence of constriction anywhere."[7] The primary change then would appear to be an acute inflammation of the tissues of the appendix, and even in the more serious cases with localised or generalised suppuration it is by no means rare to find no pathological changes save appendicular inflammation. The action of micro-organisms must, of course, be borne in mind; but this I believe to be a factor in the later, and not in the earlier, developments of appendicitis. It is opposed to all our knowledge of physiology to maintain that the healthy intestine, in whole or in part, is unable to protect itself against the micro-organisms which are normally present, and in considering the pathology of appendicitis in its earlier stages the first step is to explain the nature of the defect in the protective mechanism by reason of which micro-organisms have been able to penetrate the walls of the intestine.

As all writers admit that in many cases of appendicitis the theory of local causation does not seem to apply as far as any positive evidence exists, it seems only natural to inquire whether constitutional agencies may not be concerned in the production of such cases. Here again the analogy of the tonsil is a useful one. The protective function of the tonsils, and the circumstances under which this breaks down, have been described by Dr. Sims Woodhead, and his remarks may, I think, be equally well applied to the vermiform appendix. He says: "So long as the tonsils with their accessory lymphoid tissue forming this protective ring for the pharynx remain healthy, or so long as they are attacked by no extraordinary number of pathogenic micro-organisms, they are capable of resisting attack and of dealing with micro-organisms, even of what would be called a most virulent type. In this, of course, they are helped by the epithelium with which the lymphoid structure is invested, but some, at any rate, of the work appears to be performed by the wandering lymphoid cells of which I have spoken."[8] The tonsils may be regarded as the first line of defence in the alimentary tract; other protective agencies exist in the secretions of the stomach and intestines and in the scattered lymph follicles of the small and large gut, but from the anatomical and physiological considerations mentioned above it may not be amiss to regard the vermiform appendix as the second line of defence.

The failure of this defensive mechanism must next be considered. If an irritant poison, such as that of rheumatism, is circulating in the blood, it will manifest itself by local irritation and inflammation in certain susceptible tissues. Such a condition is present in the case of rheumatic tonsillitis, in which the inflammation attacks primarily the tonsils, and may extend thence to the pharynx, soft palate, and the deeper structures of the neck. Similarly in the case of appendicitis we may have a constitutional poison manifesting itself by an inflammation of the lymphoid tissue in the appendix; and an extension of this inflammation to the mucous membrane, the adjacent peritoneum, and the cæcum. Other pathological changes which are commonly met with—such as cystic dilatation, catarrh, concretions, &c.—will result from such inflammatory attacks. In course of time also these attacks will permanently injure the lymphoid tissue, limiting its production of lymphocytes and lessening its powers of resistance; and consequently the bacteria of the adjoining part of the intestine will increase in number and will eventually be able to penetrate the appendix and cause the more virulent and septic forms of appendicitis. While not denying the existence of purely local or mechanical causes of appendicitis, I believe that in certain cases the pathology is as sketched above—namely, (1) the presence of a constitutional poison, producing (2) inflammation of the lymphoid tissue in the appendix, which is thereby deprived of its normal protective functions, and is so weakened that there may follow (3) the entrance of micro-organisms and septic appendicitis or peritonitis.

The question as to whether any connexion exists between appendicitis and constitutional disease is one of considerable importance from a therapeutic standpoint. We have seen that anatomically and pathologically the appendix and the tonsil are very similar, and it is now recognised that an attack of tonsillitis is a common occurrence in subjects of the gouty or rheumatic diathesis. In such cases, moreover, the disease yields more readily if constitutional as well as local remedies are employed. As regards appendicitis, if it can be shown that a family history of gout or rheumatism is frequently present, and that other manifestations of gout or rheumatism are found to coexist or alternate with appendicular symptoms, it may fairly be claimed that there is at least presumptive evidence of a causal connexion between these affections and appendicitis. Such evidence I have tried to adduce in a series of cases published elsewhere.[9] The literature of the subject does not supply much information, as authors in describing cases of appendicitis have seldom given a detailed account of the family history or previous illnesses. Dr. Haig[10] thinks that nearly all cases of perityphlitis have a gouty origin and are caused by the deposition of uric acid in the fibrous tissue of the cæcum. This may be so, but, on the other hand, the tendency now is to ascribe the vast majority of all cases of perityphlitis to appendicular disease, a view which is constantly deriving additional support from the indisputable evidence presented at operations and necropsies. In this connexion I wish to refer to a case of "rheumatic perityphlitis" recorded by Dr. Burney Yeo.[11] The patient was a girl aged eighteen years who was admitted into hospital suffering from pains in the arms and knees and right iliac region, accompanied by sickness. The case is described at length, and Dr. Yeo's comment is as follows: "Extremely rare though the occurrence is, there can be no doubt that this was a case of rheumatic perityphlitis. The intercurrence of rheumatic arthritis of the joints of the right arm, the previous history of acute rheumatism, the endocarditic murmur, the complete and rapid disappearance of the local symptoms, and the sudden fall of temperature on the administration of sodium salicylate are facts which leave no room for doubting the rheumatic nature of this attack of local peritonitis." With this statement all who read the case will, I think, be in perfect agreement, but when Dr. Yeo remarks that "the case proves as clearly as possible that clinically we may have a true perityphlitis without any necessary involvement of the appendix" his position is open to criticism. He admits that to English, American, and German physicians rheumatic peritonitis is almost if not entirely unknown, and supports his own view by a reference to a list of fifteen cases collected by Spillman and Ganzinotty.[12] These have been analysed by Mr. Treves, who considers that "the evidence upon which the pathological assumption depends is by no means satisfactory and will not stand a critical examination."[13] Further, the whole of the clinical symptoms were identical with those which are now regarded as typical of appendicitis, and at one period Dr. Yeo, "bearing in mind the predominating tendency to regard all inflammatory attacks in this region as probably connected with some suppurative affection of the appendix, discussed the advisability of calling a surgical colleague into consultation with the view of some possible operative exploration." This tendency to associate peritonitis when localised in the right iliac fossa with appendicular disease is much strengthened, as already stated, by the early operations of American surgeons in similar cases, and as Dr. Yeo is unable to disprove this etiology I venture to regard his case as one of "rheumatic appendicitis."

Amongst the predisposing causes of appendicitis age is acknowledged to be an important factor, and as the activity of lymphoid tissue is greatest during early life its liability to inflammation in young subjects is not to be wondered at. Abdominal pain in children is frequently localised in the right iliac fossa, and it is probable that repeated slight inflammatory attacks of appendicitis may impair the function of the lymphoid tissue and predispose to the more serious forms of the disease. A similar tendency is observed in connexion with the tonsils, which are frequently found to be much enlarged and indurated, and yet the preceding inflammatory attacks may have been so slight as almost or entirely to have escaped observation. Sir Dyce Duckworth [14] finds that cold is frequently the immediate cause of appendicitis. Numerous cases have been recorded in which exposure or violent exercise in apparently healthy individuals was the immediate precursor of an attack. As the appendix is an extremely well protected organ as regards external influences, it seems natural to assume that in such cases, as in rheumatism generally, the illness is determined by a general chill which manifests itself locally in a susceptible organ. Talamon has observed that heavy eaters are liable to appendicitis, and to this cause he traces the frequency of the affection in England and in America. He says that an indigestible meal is often quickly followed by an attack of acute appendicitis, and this sequence of events is explained by the induction of increased intestinal movements, which drive a fæcal mass into the appendix. In fact, according to his theory there exists an unfortunate class of individuals who possess a cæcum always ready to discharge a fæcal concretion, and an appendix always ready to receive it, but unwilling to part with it. On the other hand, it may be pointed out that a tendency to rheumatism in those who live freely is well known, and an attack of gout or rheumatism frequently follows a heavy meal owing to the absorption of the noxious products of incomplete or perverted digestion. The local manifestations in such cases will vary in different individuals, but in some they would appear to take the form of appendicitis. As regards the clinical signs and symptoms of appendicitis, it is well known that these, as in the case of tonsillitis, may at first point to constitutional disturbance and that there may be nothing to direct attention to the appendix for one or two days. Thus, malaise, headache, nausea, sickness, general aching pains, pyrexia, loss of appetite and furred tongue, constipation or diarrhœa are frequently found to precede any pain or discomfort in the right iliac region, and these are suggestive of a constitutional dyscrasia as the primary disease. Dr. Kelynack [15] has recorded the case of a medical student who was suddenly seized with an acute illness of which the only definite local sign was tonsillitis, and diphtheria was suspected. On the following day abdominal symptoms appeared, and he died three days later from gangrenous appendicitis and acute suppurative peritonitis. It seems only natural to conclude that the appendix must have been weakened by some previous attacks, and the simultaneous onset of tonsillitis points to a constitutional cause. I have already referred to the occurrence of slight attacks of appendicitis in childhood, and I believe that these are much more frequent than is generally supposed. Such attacks are not considered worthy of more than domestic treatment, and just as rheumatism is ignored under the familiar name of "growing pains," so an attack of appendicitis is regarded as merely a form of "stomach-ache." The relapsing or recurrent form of appendicitis is characterised by a series of attacks repeated at irregular intervals, and tending in some cases to a condition of chronic ill-health. The relapses are extremely difficult to explain on any theory of local mechanical causation, and it is in this class of cases more especially that Talamon's theory of fæcal concretions appears to me to fail completely. On the other hand, if a constitutional disease such as rheumatism is present, and if it manifests itself by an attack of inflammation in the appendix, we shall at once recognise a liability to the recurrence of inflammation in the same organ. Such a view both coincides with our knowledge of rheumatic disease generally and explains the frequency of recurrent attacks of appendicitis.

If the above statements as to the pathology of simple appendicitis, to which I have been referring more particularly, be accepted the treatment to be adopted will be both constitutional and local. While fully admitting the frequent occurrence, even in previously simple cases, of symptoms demanding immediate surgical interference, I differ entirely from those who hold that all cases of appendicitis ought to be regarded as surgical from the outset. Such an opinion seems to exist in America, and one of the most recent writers on the subject, Dr. G. R. Fowler,[16] says that "the less medical treatment which cases of appendicitis receive the better." In this country, however, such extreme views have not yet been generally accepted. Mr. Treves, who has shown the value of operative treatment in suitable cases of relapsing typhlitis, states that "the cases adapted for operation are comparatively few, and the simplicity of the surgical treatment has rather cast into the shade the somewhat neglected measures of the physician."[17] In an attack of acute appendicitis in a rheumatic patient the symptoms will often subside rapidly on the administration of full doses of salicylic acid or its compounds. It is also advisable to clear out the bowels by means of two or three grains of calomel, followed by a Seidlitz powder, and to keep up this action by repeated doses of some mild saline. By this means we are able to prevent the accumulation of putrefactive products in the cæcum and the consequent risk of septic absorption. Even if diarrhœa is present from the outset, as occasionally happens, it is no contra-indication to the use of mild salines, for the diarrhœa is often caused and maintained by the presence of some irritant in the intestine, and the sooner this is removed and the accompanying putrefactive changes checked the better. Opium tends to conceal the symptoms, but if the local pain be excessive a fomentation containing opium and belladonna may be applied over the right iliac region. Rest in bed, warmth, low diet, and the use of local antiphlogistics represent the other details of treatment which are generally approved of. In the relapsing or more chronic forms of rheumatic appendicitis the life of the patient must be ordered and supervised as in rheumatism generally. Special attention must be paid to the condition of the bowels, so as to prevent any accumulation. Some medicine, such as cascara sagrada, is to be taken regularly, and with this may be combined naphthalin (Watson Cheyne), or salol (Treves), or creasote as an intestinal antiseptic. The prolonged use of small doses of salicylate of soda will be found useful in preventing a repetition of the attacks.

A FATAL CASE OF JAUNDICE WITH CEREBRAL SYMPTOMS.

BY SIDNEY H. SNELL, M.D. LOND.,
LATE HOUSE PHYSICIAN, HOUSE SURGEON, &C., UNIVERSITY COLLEGE HOSPITAL, LONDON.

WITH A REPORT ON

THE MICROSCOPICAL APPEARANCES OF THE LIVER.

BY THE LATE F. V. BUNCH, F.R.C.S. ENG.,
FORMERLY SURGICAL REGISTRAR, UNIVERSITY COLLEGE HOSPITAL.

THE patient was a woman aged twenty years. She had two months previously consulted me for amenorrhœa, which I found to be due to a three and a half months pregnancy. There was a marked phthisical family history, her mother having died from that disease, and since the patient's death her father and a sister have also succumbed to phthisis. In addition, at the apex of the patient's right lung there were signs of some old fibroid trouble. The onset of the present attack was as follows. On Nov. 18th, 1893, the patient seemed to be in her ordinary health and went to London to be married, she being then five and a half months pregnant. She remained at her mother-in-law's house till Nov. 20th, when she returned home feeling a little unwell and complaining of indigestion. This feeling continued, and on Nov. 23rd her friends observed that she became slightly jaundiced, vomited occasionally, and refused all food. I saw her first on Nov. 25th in the evening and found her very deeply jaundiced and complaining of severe pain in the right side and general depression. Her manner was a little strange, but she was perfectly sensible; her breathing was rapid (30), the pulse 70, and the temperature 99° F. On examination there was great tenderness over the hepatic area

Digitized by Google

corresponding with the site of the pain, and marked diminution in the superficial dulness of this area was manifest on percussion. The edge of the liver could not be felt. Splenic dulness was well marked. Nothing abnormal could be detected elsewhere by physical examination, save the old patch of tubercle before alluded to at the apex of the right lung. The fœtal heart was distinctly audible. The urine was dark in colour and contained bile pigment in abundance and a trace of albumin. On evaporation to one-fourth of its bulk and the addition of nitric acid no crystals of urea nitrite were obtained, showing the loss of urea. Repeated evaporations and microscopical examinations of different samples failed at any time to detect the least trace of crystals of either leucin or tyrosin. Owing to pressure of practice, distance from town, &c., a more complete analysis of the urine was not possible. On Nov. 26th the patient was clear and sensible, although she had had some delirium during the night. An expression of intense anxiety pervaded the features; the breathing had increased in rapidity (37), the tongue was brown and dry, the temperature was 100°, and the pulse 82. Early in the morning the patient had vomited a large quantity of altered blood having the appearance of coffee grounds. The bowels had acted twice, the motions being clay coloured. She altered little during that day, but complained of headache and persistently refused nourishment. Towards night mild delirium again came on. On Nov. 27th, at 2 A.M., the patient suddenly became totally blind, retaining only the perception of strong direct light. Later in the morning the delirium passed off and the patient again became quite rational, but complained strongly of the pain over the hepatic region. At this stage her pupils were contracted to pin point-size. The superficial liver dulness, steadily lessening, had by that time entirely disappeared. On the evening of the same day delirium of a much more violent type appeared, and her temperature, taken in the axilla, was 101°, the respiration 38, and the pulse 140. During that night convulsions supervened, and the jaundice, which had improved a little, became very much deeper. On the following morning (Nov. 28th) the patient became quite comatose, with now and then an occasional convulsion. The pupils had become, with the onset of the coma, widely dilated. The patient died early on Nov. 29th, just ten days after the first feelings of malaise and only seven days after the first appearance of jaundice. There were throughout no ascites and no hæmorrhages under the skin, nor was any itchiness complained of.

With the greatest difficulty I obtained permission for a partial necropsy. On exposing the liver I found it to be much smaller than natural and to be shrunk away towards the back, this accounting for the loss of superficial dulness. It weighed, as nearly as I could guess, about thirty ounces—under two pounds certainly—and was quite firm. The gall-bladder was empty. On the surface numerous yellow patches could be seen on the red ground, and on section the organ was dark-red, mottled with yellow. The spleen was enlarged and congested. A few pieces from different parts of the liver were secured, and beyond noticing the absence of peritonitis and fluid in the abdomen &c. I had to make a hurried conclusion owing to the objections of the family. The late Mr. F. V. Bunch—whose recent lamentable death from diphtheria, contracted in the discharge of his duties as surgical registrar to University College Hospital, is to be deplored—made the following report on the microscopical appearances of the liver:—

"Pieces of liver were handed to me hardened in alcohol. The capsule was not thickened; it stripped easily, leaving a slightly granular surface. On the greater part of the cut surface the lobular arrangement of the liver substance was clearly seen; over a few scattered areas it was, however, lost. Sections were cut by the paraffin method and stained on the slides, some with Ehrlich's hæmatoxylin, others with gentian violet and eosin. The sections show much connective tissue arranged for the most part in a perilobular manner, and to a less extent in the centres of the lobules and between the columns of liver cells. Different parts show very varying amounts of connective tissue. Where the change is most advanced there are large tracts in which liver substance is only represented by a few islands of hepatic cells, many of which contain droplets of fat. Granular masses of pigment are also seen. Numerous branching ducts lined with cubical epithelium are present. Where the process is least advanced the liver lobules are large. The centres of the lobules are occupied by a loose-meshed reticulum of connective tissue in which a few liver cells undergoing fatty degeneration are enclosed; the change becomes less marked in the zone surrounding this; and in the greater part of the lobule the liver cells are quite healthy. Ducts are plentiful in the perilobular areas. The connective tissue everywhere takes the form of a loose meshwork richly supplied with oval and spindle-shaped nuclei. There is, in places, a considerable infiltration with small round cells. There are no hæmorrhages, and crystals of leucin and tyrosin are not seen. The vessels are healthy. Many examples of division are seen in the nuclei of the liver cells. The appearances of the liver differ from those described in ordinary cases of acute yellow atrophy in the formation of connective tissue; the degeneration of the liver cells is only seen where this connective tissue is formed, and there is therefore a large number of cells showing no deviation from the normal. The probable pathological process seems to have been an acute formation of fibrous tissue, the destruction of liver substance being secondary."

It will be noticed that this fatal case of jaundice with cerebral symptoms occurred in an unmarried pregnant girl; that is the class of patient attacked in so large a proportion of the cases of that rare disease, acute yellow atrophy of the liver. But although during its clinical course I had but little doubt that such was its nature, on reviewing all its aspects, and especially on studying the microscopic appearance of the diseased organ, it becomes at once evident that striking points of difference exist which mark it out from the usual run of cases of acute yellow atrophy of the liver. Thus the course was much more rapid, there was complete absence of leucin and tyrosin from the urine or from the liver sections, and there was no tendency to hæmorrhages (apart from the hæmatemesis) and no sign of abortion. The sudden onset of amaurosis I have failed to find elsewhere recorded. Again, pathologically, the liver, instead of being very flaccid, was actually firmer than natural. Microscopically, the appearances were suggestive of an acute cirrhosis rather than an acute atrophy. I knew the patient's family well, and I made very careful inquiries about her former habits, being specially incited thereto by the warning which Dr. Poore gives in his eloquent lectures on forensic medicine to always be on the *qui vive* for phosphorus poisoning in cases of acute yellow atrophy. Accordingly, at my very first visit, having managed to send all her friends out of the room, I asked the girl whether she had been taking anything to tamper with herself &c. To this question she gave a most emphatic denial and with every appearance of truthfulness. Inquiries from the friends elicited that although owing to her pregnant condition she underwent a great deal of mental worry, yet before the visit to London she became very cheerful at the prospect of being married, and, indeed, this event removed the very reason for any question of tampering. One fact was obtained which might have some bearing on the case—i.e., that the patient was in the habit of eating very large quantities (three or four pennyworth daily) of those small pink cachous used for clearing the breath of smell. I endeavoured to obtain some of these from the same source, but failed. On consulting chemists and sweet manufacturers, however, I am told that it is to the last degree improbable that these would contain phosphorus. I think it may fairly be said that the presence of phosphorus poisoning in this case is, at all events, "not proven." With regard to the question of alcoholic excitation, this in its turn may be also excluded. The patient was one of a tectotal family, belonged to a temperance society, and had never tasted alcohol in her life, according to her statement.

The case is obviously one to be recorded while waiting for further similar cases to throw a light on its exact nature. It is, of course, a matter for regret that the necropsy was so slightly and hurriedly performed; but I encountered the most strenuous opposition from the family.

Grays, Essex.

AN EXTRAORDINARY STORY OF WHOLESALE POISONING.—A story has reached us from Heath Town of wholesale poisoning by soup which in some of its particulars reminds us strongly of the Wylde Green cases which occurred during the Christmas week of last year. Nine persons, ranging in age from three to eighty-one, partook of some soup distributed in charity from the vicarage, and all afterwards showed symptoms of poisoning. In one sad case death ensued.

THE IMMUNISATION OF HORSES FOR THE PREPARATION OF DIPHTHERIA ANTITOXIN.[1]

BY WILLIAM ROBERTSON, M.R.C.V.S.,
ASSISTANT, VETERINARY DEPARTMENT, BRITISH INSTITUTE OF PREVENTIVE MEDICINE.

IT is my intention to describe to the best of my ability the method employed in the immunisation of horses for the preparation of diphtheria antitoxin, and also to describe the process of bleeding these animals when immune. I find that suitable horses of the heavy draught class can be purchased for prices varying from £3 10*s.* to £7. The animal is, in the first instance, placed in an isolation box, where it is tested with mallein (generally twice), then with tuberculin, and if the test is negative it is placed amongst the other horses. The seat of inoculation which I find most convenient is just in front of the shoulder; this part is easily accessible in the horse, and the operator is less liable to be kicked by the animal. Previously to inoculation the syringe &c. are boiled for fifteen minutes and the part washed with ether and then with a solution of carbolic acid (1 in 20). The syringe, with needle affixed and charged with toxine, is then held in the right hand and a fold of sterilised skin pinched up with the left, the needle inserted, and the piston pushed gently home. As a rule the horse stands quietly enough and seldom exhibits any symptoms of pain or uneasiness during the inoculation. In commencing the immunisation of an animal very small quantities of the toxine are used at first, the initial dose being generally 1 c.c. In the case of the first horse experimented on I used toxine mixed with Gram's solution of iodine, but this method was soon discontinued, as it was found that the solution of iodine acted as an irritant and caused local swelling slow of absorption. The local lesion following the first inoculation is, as a rule, well marked and appears in the form of a diffuse soft swelling slightly painful on pressure. This swelling reaches its greatest height in from six to seven hours after inoculation, generally persists for two or three days, and then disappears. Coexistent with the local lesion we generally get a rise in temperature. This rise reaches its maximum in from six to seven hours after inoculation—that is to say, at the same time at which the local swelling is greatest—and generally falls to normal in thirty-six hours. When the local lesion has disappeared and the temperature fallen to normal the dose of toxine is repeated, and if this produces very little local or general effect it is raised by degrees, thus: primary dose, 1 c.c.; then after a week has elapsed, 1 c.c. again; then 5 c.c.; then 10 c.c.; then 10 c.c. again; then a rise to 25 c.c., and so on. When the dose has reached 50 c.c. we give the horse this quantity three times a week for a fortnight, and if the animal stands this amount without any reaction the dose is raised to 100 c.c. three times a week for the same length of time, and then 200 c.c. at the same intervals. The period of time allowed to elapse between each inoculation varies with different animals, and we take as a guide the local swelling and the temperature, as the inoculations are discontinued until both have subsided.

The above is the outline of the method of immunising horses, but I have noticed a few facts in connexion with the above remarks which are of some interest, but which are of a somewhat disjointed nature. No two horses are alike in their power of resistance to the action of diphtheria toxine. I have had an animal under my charge which received 10 c.c. toxine, and the day after received 100 c.c., and this without producing any very marked effect; while in another case the initial dose of 1 c.c. produced a violent local and general reaction, and after an interval of a fortnight a second dose of 2 c.c. caused paralysis of the hind quarters and the animal had to be destroyed. The same toxine was used in both cases. Again, in some animals the local lesion in the neck disappears twice as fast as in others, using the same toxine in both cases. The rise in temperature following inoculation is also very variable. I have a record of a horse whose temperature during the whole process of immunisation never exceeded 103° F., and I have a record of another horse also immune who after every inoculation had a rise in temperature, in one case exceeding 105°. Amongst all the horses I have inoculated, even when the temperature was very high, I have never known one to refuse its food; but I have noticed that following on a large dose of toxine some animals have a fit of shivering and exhibit distinct rigors. In a very few cases—four out of many hundreds of inoculations—I have seen necrosis of the skin to follow inoculation. The skin over the swelling becomes brown and hard, and on falling off leaves a glazed red surface; this, however, soon heals under a boracic acid dressing. When the horse is considered to be sufficiently immune it is allowed to rest for a clear week from the last inoculation before being bled. The vein from which we bleed is the jugular vein found on the side of the animal's neck lying in what is termed the jugular furrow and separated from the skin by the panniculus carnosus, that sheet of muscular tissue stretching subcutaneously over the upper part of the horse's body. The part over the vein is first shaved and then washed thoroughly with ether and carbolic solution (1 in 20). The vein is then raised by pressure with the fingers, and with a scalpel a small incision about half an inch in length is made through the skin and panniculus carnosus.[2] On separating the edges of the wound with a pair of forceps the vein can be observed at the bottom of the incision. The cannula, after being connected to the Kitasato flask by a piece of quarter-inch rubber tubing, is taken in the right hand, the vessel is raised with the left and the tube inserted, care being taken that the stream of the vein is not interfered with. The blood then flows freely, and when the flask is sufficiently full it is replaced by an empty one as follows. The rubber tube is pinched by the fingers of the left hand and the full flask withdrawn and handed to an assistant to plug. The empty flask is now taken in the right hand, the long glass tube is placed in the end of the rubber piping, the constricting fingers are withdrawn, and the blood flows.

As regards the amount of blood which can be removed from an animal with impunity, that of course varies with size. The amount I generally take is ten litres, but I have removed as much as sixteen litres without any injurious effect to the horse; this is not to be wondered at, seeing that one-sixteenth part of the animal's body weight is blood. The reason why I do not as a rule draw off more than ten litres at a time is that if more is taken I find the last four or five litres over the tenth do not clot properly, and the serum which separates is of a pink colour. As soon as the blood is firmly clotted it is advisable to twist the flask in the hand, so as to separate the clot from the walls. When sufficient blood has been drawn off I press on the vein anterior to the cannula and withdraw the tube. I then sponge gently with carbolic solution (1 in 20) and fasten the edges of the wound with two catgut sutures. The wound is now dusted with iodoform and covered with a piece of sterilised wool dipped in collodion. I have never had any difficulty in stopping bleeding, and the wounds have always gone on satisfactorily. The veins are in no case obliterated or obstructed, and in one horse which has been bled fourteen times the vessel is just as pervious as in any other animal.

It is hardly necessary for me to state that all instruments &c. are boiled for half an hour previously to an operation. As regards methods of restraint in this operation, these of course depend upon the animal, but I have usually found horses stand quietly enough when being bled. I should like to say a few words about the flasks in which the blood is collected and the method of decanting the serum. The flasks are ordinary Q-like filtering flasks fitted with a rubber cork and two pieces of glass tubing, one of wide calibre to allow escape of air, the other of narrower dimensions, over the orifice of which is slipped the rubber tubing connected to the cannula. These flasks are sterilised for three hours on three separate occasions. When the flasks are full and the blood has been twisted on clotting they are placed in a cool cellar, and in twenty-four hours' time a large amount of serum will have separated. The branch tube of the flask is flamed in a spirit-lamp, the wool plug removed, and the serum poured off into sterilised

[1] A paper read before the Pathological Society of London on March 19th, 1895.

[2] At first the cannula was inserted directly into the vein through the skin, but afterwards it was found to be more satisfactory to make an incision.

Digitized by Google

Winchesters. The branch tube is now wiped free from serum by repeated pellets of sterile wool, and it is finally replugged. As a rule, a two-litre flask of blood yields one litre of serum, but some horses' blood does not yield anything like that amount.

Sudbury.

AN UNUSUAL CASE OF MULTIPLE HERNIA WITH HYDROCELE; STRANGULATED FEMORAL HERNIA; OPERATION; RECOVERY.

BY ETHELBERT COLLINS, L.R.C.P. LOND., M.R.C.S. ENG.

THE patient, a man aged sixty-five years, had on the right side a complete inguinal hernia and a femoral hernia, and on the left side an incomplete inguinal hernia. There was also a hydrocele of the right tunica vaginalis. According to the patient's statement both inguinal herniæ appeared about ten years previously, and were caused by lifting heavy weights; he was, however, uncertain as to the duration of the femoral hernia. The hydrocele had existed about six years, having been regularly tapped twice a year. On the morning of Jan. 4th, 1895, I was summoned to this case "as one of the man's ruptures had come down, and he was unable to get it back." When I saw him (about three hours after his rupture had come down) he presented the symptoms of a case of strangulated hernia, he had vomited several times, there was distressing hiccough, and pain in the region of the hernia and at the umbilicus. On examination I found that the femoral hernia was strangulated; it was about the size of a large walnut, tense, hard, and there was no impulse on coughing. I was unable to reduce it. I again saw the case in the afternoon with my brother, Mr. J. B. Collins, and we agreed to operate. After the patient had been fully anæsthetised I again tried to reduce the hernia, but was unsuccessful. Having first tapped the hydrocele, which was rather in the way, as it contained twelve ounces of fluid, I proceeded to operate in the usual manner. The sac was excessively thick, and contained a small quantity of clear fluid and a knuckle of intestine; it was tightly gripped in the femoral ring. After making a few notches in Gimbernat's ligament the gut was easily returned. I then ligatured the sac with carbolised silk and removed it, closed the wound, and dressed it with sal alembroth gauze and wool. Carbolic acid was used during the operation, and all the antiseptic precautions it was possible to take in an ordinary cottage were observed. The patient made an uninterrupted recovery, no rise of temperature or any unfavourable symptom occurred, and he was able to leave his bed on the twelfth day after the operation with the wound perfectly sound. On Feb. 11th he was in good health and, wearing a suitable truss, was walking about as usual.

I quote this as being an unusual case of herniæ complicated with hydrocele. I cannot recall a case of double inguinal hernia and a femoral hernia in the same subject, leaving the hydrocele out of the question. Of course, it is not surprising that the femoral hernia should have become strangulated, as the man was wearing a double inguinal truss—which he had obtained from some quack—leaving the femoral hernia to take care of itself. Before I ventured to record this case I sought the opinion of my friend and former teacher, Mr. C. B. Lockwood, as to whether he considered it worth publishing. His large experience and original work on this subject, together with his concordance with my views, form my excuse for doing so. I may add that Mr. Lockwood suggested that the man had an abnormally long mesentery, which might account for his several herniæ, and certainly the shape of his abdomen would indicate that he has, it being flattened above and bulging below. I am indebted to my brother for his valuable assistance, to which I largely attribute the success of the operation.

SUPERNUMERARY MAMMA IN A MAN.

BY W. F. ADAMS, M.R.C.S. ENG., L.R.C.P. LOND., FORMERLY HOUSE SURGEON TO KING'S COLLEGE HOSPITAL.

WHEN I was at the Kashmir Mission Hospital last summer a Hindu pundit aged about thirty-five came to me for some gastric ailment. When about to examine his abdomen I noticed a tumour above the left hip. This proved to be a fully developed mamma, as seen in the accompanying engraving, which is from a photograph taken at the time. In consistency and appearance it was exactly

like the mamma of a virgin. The nipple was small and rather flattened, but the areola was perfect. I was unable to express any milky fluid. The man told me that it had developed at the time of puberty and never gave him any annoyance. He, therefore, did not desire its removal. His proper nipples on the chest were quite normal, and I detected no trace of other abnormalities. I believe the position, though not the commonest, is not unusual for supernumerary mammæ, but its large size and the fact of its occurring in a man seem to me to make this case worthy of record.

SINGULAR COMPLICATION OF DEATH FROM DROWNING: IMPACTION OF A PIECE OF COKE IN THE LARYNX.

BY WILLIAM EVANS, M.R.C.S., L.R.C.P. LOND.

THE following case is perhaps worthy of being recorded on account of the remarkable circumstances attending it. A boat containing six persons was capsized in the river Thames, near Wandsworth Pier, on Bank Holiday (Aug. 5th), and two of the party lost their lives. The body of one of them, a man aged about twenty-one years, was recovered on Aug. 9th, and I made a post-mortem examination on the following day. Having opened the chest, I observed that the lungs were not distended and nearly overlapping the heart, as is usual in death from drowning, neither did they pit on pressure. I removed the tongue, larynx, &c. complete with the lungs, and found a piece of coke firmly impacted in the larynx, the vocal cords grasping it a little below its centre.

Digitized by Google

This was of irregular shape, flattened, and broadest in the middle, from which it tapered to each end. The extreme measurements were 1⅜ in. long, 1 in. wide, and ¼ in. thick. Where encircled by the vocal cords the extreme measurements were ½ in. by ⅜ in. The narrow tapering end was directed downwards. The lungs were only slightly crepitant and contained little or no frothy fluid. The other signs were those of asphyxia.

Pimlico-road, S.W.

A CASE OF ACUTE YELLOW ATROPHY OF THE LIVER.

By D. J. COLLINS, M.B., B.Ch., B.A.O. R.U.I.,
SURGEON-LIEUTENANT, ARMY MEDICAL STAFF

A PRIVATE of the 4th Battalion Rifle Brigade, aged nineteen, was admitted to the Station Hospital, Devonport, on Feb. 25th, 1894, with syphilitic iritis. The orthodox treatment was adopted, and by March 25th all traces of the inflammation of the iris had disappeared, when a yellowish tinge was noticed in the skin and conjunctiva. He complained of severe headache, anorexia, and intolerance of light; there were no fever, no hepatic tenderness, and no enlargement of the liver. The patient had never been to India and had never previously suffered from any liver trouble. On March 27th the jaundice was more intense, there were considerable bilious vomiting, severe headache, clay-coloured motions, and bile-stained urine, the temperature was normal, and there was no hepatic tenderness. The area of liver dulness appeared to be diminished, and the possibility of acute yellow atrophy suggested itself. On March 28th cerebral symptoms became marked, with restlessness, delirium, and convulsive twitchings. The vomit presented a coffee-ground appearance; the pulse was quick and full, 120 to the minute; and the tongue was dry and brown. The liver area was markedly diminished, but pain and tenderness in the hepatic region were absent. On March 29th the patient was comatose, with stertorous breathing and dilated pupils; the liver dulness had quite disappeared, both in front and behind, the liver area being replaced by intestines. The temperature was 100·2° F., the pulse 136, and the respiration 40. The urine contained bile pigment, some blood, leucin, and tyrosin. The patient died at 11 A.M. on March 30th. A post-mortem examination was made on March 31st. The body was well nourished and the skin a deep yellow colour. The liver was much diminished in size, soft and flabby, and weighed only twenty-three ounces. The capsule was wrinkled and looked almost like a bag with fluid contents. The surface was of an orange colour, with patches of dark red and purple; the section was of a dark-yellow tint, in some parts bright red, and in others entirely yellow. The gall-bladder and bile-ducts were empty; the spleen was enlarged and the heart and kidneys had undergone fatty degeneration; the endocardium was stained with bile. Treatment was symptomatic. This case is interesting in its extremely acute course, only five days elapsing between its first onset and the death of the patient; and in that the liver, which was exhibited at the Plymouth Medical Society, was extremely small in size, even for this peculiar disease, weighing, as above stated, only twenty-three ounces.

AN UNUSUAL AND REMOTE SEQUELA OF OVARIOTOMY.

By WALTER FALLA, M.R.C.S. ENG., L.R.C.P. LOND.,
SURGEON TO THE JERSEY GENERAL HOSPITAL.

A WOMAN aged fifty-two was admitted into the Jersey General Hospital on April 12th, 1894, suffering from a large ovarian cyst. On April 17th I performed the operation of ovariotomy. The cyst was unilocular and quite free from adhesions. The pedicle being rather broad, it was transfixed and tied in the usual way with a stout silk ligature and the abdominal wound closed with a few silk sutures, which were removed on the eighth day, the wound having quite healed. The highest temperature recorded was 101·6° F. on the fourth night, after which it was normal. On May 3rd the patient got up for the first time, sixteen days after the operation; she made an uninterrupted recovery and was discharged from the hospital quite well on May 17th, a month after the operation. She continued in perfect health until the end of December last, when she said she first felt pain on micturition, but did not have any medical advice for it. In April she noticed a little blood in the urine. These symptoms, the patient said, continued and gradually became worse until she consulted me on June 30th last. She then had all the symptoms of stone in the bladder, but would not submit to an examination. On July 19th she again consulted me as she was in great pain, and the following day I sounded the bladder and found a calculus approximately one and a half inches long and three-quarters of an inch broad. On July 26th, with the assistance of Mr. Bentlif and Mr. Sullivan, I performed the operation of lithotrity. The calculus was phosphatic and was easily crushed. On attempting to withdraw the lithotrite I found it impossible to do so without using undue force, but after some further crushing and manipulation I was able with more or less difficulty to withdraw the instrument, when between the blades I was astonished to find a thick silk ligature covered with a certain amount of phosphatic deposit, which easily accounted for the difficulty I had just experienced. The bladder was afterwards washed out in the usual way and all the fragments removed. The patient had no bad symptoms and in a few days was practically well. On examining the ligature carefully I found that it was undoubtedly that which had been used for tying the pedicle of the ovarian cyst.

Remarks.—It seems difficult to understand how a ligature used in tying the pedicle of an ovarian cyst could ultimately become the nucleus of a vesical calculus in a case in which there was no injury to the bladder during the operation and no difficulties whatever connected with it, the patient continuing in perfect health for about nine months afterwards. It is also remarkable how the ligature, which must have set up a certain amount of irritation and which eventually perforated the bladder, could do so without giving rise to any symptoms until it became lodged in that viscus.

GUY'S HOSPITAL.

CASE OF FRACTURE OF OS CALCIS; UNION OF FRAGMENTS IN BAD POSITIONS; RESECTION OF PORTION OF OS CALCIS; USE OF STEEL SCREW; RECOVERY; REMARKS.

(Under the care of Mr. W. ARBUTHNOT LANE.)

THIS is one of those cases which require no comment, the reasons for the performance of the operation and the operation itself being clearly given in the account. The necessity of operation for badly united fractures has not infrequently arisen in other parts of the body, but so far as we are aware this is the first time that it has been required for fracture of the os calcis. For the notes of this case we are indebted to Mr. J. T. Roberts, dresser.

A young man aged twenty-one years was admitted into Guy's Hospital under the care of Mr. Lane for injury to the left foot on Nov. 18th, 1893. The patient lost his balance while cleaning a second-floor window, and in order to try to save himself he jumped, alighting on his feet on the pavement below after falling from a height of thirty-five feet. He was immediately conveyed to the hospital, and on admission his left foot and ankle were found to be very much swollen and discoloured. When he had been anæsthetised distinct crepitus could be felt in the os calcis by fixing the posterior part of that bone with one hand and flexing and extending the foot with the other. The line of fracture, however,

Digitized by Google

could not be felt owing to the swollen condition of the foot. As there was considerable displacement of the fragments, the foot being fixed in a position of extreme abduction, Mr. Lane wished to cut down on the os calcis and to fix the fragments in their normal position by means of steel screws, but the patient would not hear of such a procedure. Consequently the foot was fixed in as good a position as possible in the ordinary way, and gradually the swelling subsided and pain disappeared. On Dec. 12th a Croft's splint was applied, and he was discharged on the following day, supporting himself on crutches. He was readmitted under the care of Mr. Lane on Feb. 5th, 1894, for pain in the sole in front of the tubercle of the os calcis, the pain being so great that he could not stand on the foot. There was a hard swelling under the heel which on incision was found to be a mass of fibrous tissue, beneath which a bursa had developed over a prominent piece of bone. This was treated as effectually as possible. The patient was again readmitted under the care of Mr. Lane on account of pain and stiffness in the left ankle-joint, especially at the point where the external malleolus impacted on the displaced os calcis. He began to use his foot about three weeks after his previous discharge; but it became very painful and stiff after doing so. Finally he was unable to use it at all and he now begged to have the foot amputated. On admission his ankle was slightly swollen and there was some thickening of the os calcis below the external malleolus. Both flexion and extension of the ankle were limited, adduction and abduction of the foot were absent, and flexion and extension of the great toe were also limited. There was considerable flattening of the arch, and the foot occupied an abnormally abducted position owing chiefly to the outward displacement of the tuberosity of the os calcis. On Aug. 24th Mr. Lane broke down all adhesions in the joint and fixed the foot in as good a position of adduction as possible. On the 29th the patient was allowed to get up after dinner, but soon after doing so his foot began to be very painful, to such a degree that he could not use it, and it remained so for some time after he returned to bed. The breaking down of the adhesions having proved ineffectual, Mr. Lane decided to refracture the os calcis and screw the pieces together in a better position, it being evident that the pain was due to the altered mechanics of the ankle-joint owing to the union of the fragments of the os calcis in a bad position. An incision was made across the sole of the foot, and the os calcis was exposed. It was then divided by a chisel and mallet, and a small wedge-shaped piece of bone removed so as to allow the posterior portion of the os calcis to be displaced inwards. An incision was now made over the posterior surface of the os calcis and a long screw introduced, by means of which the two pieces of bone were brought into firm and accurate apposition—the distal piece of the os calcis having been slightly rotated in order to adduct the foot from its previous exaggerated abducted position. The wounds were then sewn up by deep fishing-gut and superficial horse-hair sutures, and sterilised dressings and splints were applied. On Sept. 4th the deep sutures were taken out, the wound having united by primary union. On the 11th the superficial stitches were taken out, the wounds having completely healed. On the 14th a Croft's plaster-of-Paris splint was put on the patient's foot, and on the 16th he was discharged. On Jan. 15th, 1895, the patient was again seen by Mr. Lane. He had been following his ordinary vocation for the previous month, walking about or standing on ladders &c. all day from half-past six in the morning until seven o'clock in the evening. He had felt no pain or weakness in his foot during that time. Sensation was normal all over the foot, and he could walk on tip-toe and hop about on the left leg with the greatest ease.

Remarks by Mr. ARBUTHNOT LANE.—This case illustrates very well the very great advantage that a surgeon can obtain by the use of the steel screw. As far as I know I could not have retained the fragments of the os calcis in the foot in a position of adduction without the aid of this very powerful mechanism, and one has the satisfaction of knowing that by its use one has converted a patient from a condition of absolute physical incapacity into one of perfect mechanical usefulness. Of course, it would have been much wiser to have fixed the fragments in their normal relationship at the time of the accident; but, as in many other cases, I found it impossible to make the patient understand the immense advantages which operative interference offered him over any other form of treatment.

SALOP INFIRMARY.

NOTES OF A SERIES OF CASES OF DILATATION OF THE STOMACH TREATED BY SYPHONAGE AND OTHER METHODS.[1]

(Under the care of Dr. EDWARD CURETON.)

WE bring before the readers of THE LANCET a series of cases of dilatation of the stomach which have been treated in the Salop Infirmary under the care of Dr. Cureton, the cases occurring from 1890 to 1895 inclusive. He explains that the notes refer to cases of chronic dilatation, which, as is known, is mainly due to pyloric obstruction, with or without the presence of a tumour; these cases are for the most part those of dilatation from defective tone or muscular weakness, or chronic catarrh occurring in the anæmic, or from habitual over-distension from food and drink, especially the taking largely of starchy foods, as potatoes, which generate gases, or the excessive use of aerated waters or other beverages. The patients were nearly all from the country, where a vegetable diet usually prevails to a large extent. First, with regard to the diagnosis of dilatation of the stomach, clinical evidence of this condition is afforded by the vomited matter and the time when vomiting ensues, which may be several hours after food, or again after several days have elapsed, when large quantities are usually brought up, the patient being uncomfortable and distended until vomiting occurs, when usually great relief is obtained by the emptying of the stomach; the stomach appears, however, to be only partially emptied, a residuum of sour fermenting stuff remaining behind and keeping the organ, as it were, chronically septic. Then, with regard to the vomited matters, these will usually be found to be darkish brown in colour, sour smelling, and of strongly acid reaction; a thick scum forms on the top, and a brown sediment is seen at the bottom of the vessel on standing. Most of the patients complain of acidity and of the "teeth being on edge." With regard to the physical signs, these may be well marked or again nearly all absent. The chief are a want of symmetry in the abdomen as a whole, flattening of the epigastrium, and sometimes hollowness here when distended; the "stomach note" is obtained both higher and lower down than usual, and splashing sounds can often be elicited on succussion. With regard to treatment, various drugs, as we know, have been used from time to time, but the chief object of the publication of these notes is to bring under notice the great benefit which results from the use of the stomach tube in these cases. All, or nearly all, of these cases—twelve in number—have been treated by this method. The points brought out in their treatment by drugs, diet, and syphonage are as follows: 1. As to drugs alone, they only temporarily relieve acidity and stay fermentation, but the attacks of vomiting occur again after a time. The same may be said with regard to the most careful dieting in addition to medicine; but with syphonage added to these a better result, and in some cases quite a surprising state of things, may be expected, the vomiting ceasing with the use of the tube, the pain and burning sensation and distension subsiding, and a rapid increase of flesh and strength ensuing. It will probably be found that the cases which yield the best results will be those of what may be described as "simple dilatation," such as occurred in some of these cases, the patients being country folk, hard-working men for the most part, who imbibe enormous quantities of fluid during the harvests, such as cider or "small beer," who have three meals a day, eat largely of starchy foods, drink tea freely, and also consume large quantities of potatoes, all of which tend to the generation of gases, with subsequent distension of the stomach and stretching of its walls, whereupon dilatation occurs, the food remaining in the stomach and setting up decomposition. No doubt sarcinæ might have been found in most of these cases if there had been time to look for them; they were present in the only case examined for them. Another point brought out by these cases is the relief which the tube will afford where there is malignant disease of the stomach. It has seemed to Dr. Cureton that the very fact of introducing a tube into the stomach stimulated the muscular walls to contract and diminish the size of the organ, and thus has had a more or less curative influence upon the muscular coats in cases of simple atonic dilatation. With reference to the amount

[1] Recorded before the Shropshire and Mid-Wales Branch of the British Medical Association.

Digitized by Google

of fluid used this varied a good deal; the washing out generally took place just before dinner, and was continued until the fluid used came back clear. The patients on admission were all placed on a No. 2 diet, which is the ordinary house diet of most hospitals; then, as occasion required, more milk was given, as well as prepared food and fish and beef-tea, the chief changes in diet being recorded in the subjoined cases, one article being struck off as another was substituted for it. With regard to the drugs used in washing, these were bicarbonate of soda, one drachm to a pint; sulphocarbolate of soda, half a drachm to a pint; and sulphurous acid, one drachm to a pint. Plain boiled water was often used alone. The duration of the treatment varied a good deal; but most of the patients got better fairly soon, scarcely any patient remaining in hospital over six weeks, and vomiting was hardly known to occur in any case of simple dilatation after the proper use of the tube. Another point of importance is the rapid tolerance of the treatment, and when the patient has learnt how to pass the tube for himself—that is, to swallow it—he is able and willing to follow up the treatment for himself after leaving the hospital; and when the patients are in hospital it is possible by the daily examination of the washings to judge how they are progressing. Nothing new or original is claimed for the treatment; it is only the adoption of a well-recognised form of giving more or less permanent relief to what, under other methods of treatment, are found to be chronic and unsatisfactory cases in daily practice. The following are short notes of the cases treated at the Salop Infirmary.

CASE 1.—The patient, a woman aged thirty-one, was treated in the infirmary from Dec. 20th, 1890, to Jan. 10th, 1891 (five weeks). She was placed on diet No. 2, and on Dec. 16th on extra milk. She had been an in-patient twelve months previously with similar symptoms, and an out-patient for the twelve months prior to admission. There were constant pain (epigastric) and vomiting. The stomach was markedly dilated. Treatment: creasote (1 min.) in pills three times daily, arsenic and liq. pept., and soda and rheum. The stomach was washed out by a funnel syphon with marked benefit. The patient was unable to remain under treatment and was lost sight of.

CASE 2.—The patient, a man aged twenty-three, was in the infirmary from July 23rd to Sept. 5th, 1891 (five weeks). He was placed on diet No. 2 and on prepared food (three pints). He was also given bread-and-milk, custard, fish, and cocoa. There was a history of gastric ulcer (pain, hæmatemesis, &c.) three months prior to admission. There were pain and vomiting with considerable dilatation and marked constipation. Treatment: 1. Sulphocarbolate of sodium, subnitrate of bismuth, and decoction of aloes. The stomach was washed out with warm sulphurous acid solution. 2. Hydrochloric acid, liquor strychniæ, and liquor arsenii hyd. three times daily p.c. 3. Bicarbonate of potash, salicylate of sodium (15 gr.), decoction of cinchona, liq. pept.. arsen. hyd., and carbolic acid. He was very much relieved and went out with the tube, which he continued to use.

CASE 3.—The patient, a man aged forty-nine, was in the infirmary from Nov. 7th, 1891, to Jan. 2nd, 1892 (seven weeks). He was placed on No. 2 diet, with extra beef-tea, cocoa, and mince, followed by No. 3 diet and prepared food (one pint). There were pain and vomiting eight weeks prior to admission, with hæmatemesis; also similar symptoms three weeks prior to admission, vomiting constantly small quantities of sour matter about half an hour after food. He had also mitral regurgitation. His weight was on Nov. 23rd, 9 st. 2½ lb.; on the 26th, 9 st. 1 lb.; on Dec. 5th, 9 st. 3 lb.; on the 14th, 9 st. 4¼ lb.; and on the 21st, 9 st. 6¼ lb. The symptoms continued, but not hæmatemesis. The vomit was highly fermented. There was hepatic tenderness—? pyloric tumour. Treatment: (1) subnitrate of bismuth (15 gr.), hydrochloric acid (2 min.), and tincture of opium (5 min.); (2) carbonate of bismuth, bicarbonate of sodium, compound tincture of gentian, creasote (1 min.), acetate of morphia (¼ gr.), extract of aloes—a sufficient quantity to be taken three times daily: (3) opium pill; (4) alkaline gentian mixture; (5) liquor morphiæ (10 min.), liquor pept. (half a drachm), compound tincture of cardamom (half a drachm). The stomach was washed out as above. The patient left much relieved. Carcinoma of the pylorus was suspected.

CASE 4.—This case was that of a patient aged fifty who was readmitted and stayed in the infirmary from March 25th to June 3rd, 1893. There are no notes of any value in this case.

CASE 5.—The patient, a woman aged thirty, was at the infirmary from June 10th to July 16th, 1892. She was placed on a milk diet (two pints), beef-tea (one pint), prepared food (two pints), bread-and-butter, and fish. She had been an in-patient six times before. She had been in bed since January with gastric symptoms. There seemed to be blood in the vomit. There were many carious teeth. She was very hysterical. The stomach was dilated, and there was constipation. Treatment: (1) compound rhubarb pills, compound pills of asafœtida; (2) bromide of potassium, tincture of valerian vol. The stomach was washed out with marked relief of all symptoms, but the patient would not continue the treatment.

CASE 6.—The patient, a man aged fifty-five, was at the infirmary from Aug. 27th to Oct. 1st, 1892 (one month). He was placed on diet No. 1, and later on diet No. 2, with mince and boiled milk (four pints). There was a two months' history of vomiting and pain. A small pyloric tumour was to be felt. He vomited copiously every two or three days, the vomited matter being very acid. The vomiting ceased under treatment and only occurred once since his admission. Treatment: (1) sulphite of sodium (15 gr.), compound infusion of gentian, to be taken three times daily; (2) sulphocarbolate of sodium (15 gr.), water one ounce, for washing out the stomach; (3) liquor Fowleri (2 min.), spirit of chloroform, bicarbonate of sodium, tincture of nux vomica, infusion of gentian; (4) compound pills of pepsine. The patient was very much relieved and was discharged with the tube and solution in order to continue the treatment.

CASE 7.—The patient, a man aged thirty-eight, was at the infirmary from Sept. 17th to Oct. 8th, 1892 (three weeks). He was placed on diet No. 3. Since March he had suffered from influenza; there were vomiting and pain, with marked gastric dilatation and constipation. Treatment: (1) bicarbonate of sodium, tincture of nux vomica, rhubarb powder, compound spirit of ammonia; (2) carbolic acid (1 min.) twice daily; (3) Carlsbad Sprudelsalz (2 dr.) every morning. The stomach was washed out daily with hot water. The patient was markedly relieved and was discharged with the tube.

CASE 8.—The patient, a youth aged nineteen, was at the infirmary from July 29th to Aug. 12th, 1893 (fourteen days). He was placed on diet No. 3. There had been subacute rheumatism for five months. The heart sounds were normal. The stomach was much dilated, but there was no vomiting. Treatment: (1) salicylate of soda (10 gr.) three times daily; (2) a pill of colocynth and hyoscyamus every other morning; (3) stomachic mixture. The stomach was washed out occasionally, and the dilatation was relieved.

CASE 9.—The patient, a man aged forty-seven, was at the infirmary from Feb. 24th to March 24th, 1894 (one month). He was placed on diet No. 2, with minced chop. His weight on admission was 8 st. 13 lb., and on March 22nd 9 st. 1¼ lb. For four months there were pain and vomiting daily. He vomited "dark stuff" after food. Dilatation was marked. Treatment: (1) carbonate of bismuth, sedative solution of opium, alkaline gentian mixture; (2) wood charcoal powder (1 dr.); (3) Fowler's solution, tincture of capsicum, tincture of nux vomica. The stomach was washed out daily. The patient was discharged very much relieved. He was seen six months later, when he was still washing the stomach once a week.

CASE 10.—The patient, a man aged forty-five, was at the infirmary from July 21st to Aug. 18th, 1894. He was placed on diet No. 2, with the addition of fish, minced chop, and milk. He had been an out-patient since Aug. 12th and ailing for twelve months. There were gastric pain and vomiting. He vomited only once daily. Liver dulness was diminished. Pyloric resistance was felt (under chloroform). Treatment: (1) alkaline gentian mixture; (2) creasote pills (1 min.) four times daily. The stomach was washed out daily with bicarbonate of soda. The patient obtained great relief, and was discharged with the tube, being ordered to continue this treatment. He is supposed to have died subsequently from pyloric cancer.

CASE 11.—The patient, a man aged twenty-six, was at the infirmary from Jan. 5th to March 2nd, 1895. He was placed on diet No. 2. There was a three years' history of pain after food. Two months previously there was "black" vomit. He had lost 2 st. Treatment: (1) compound gentian mixture; (2) pill of colocynth every other night; (3) creasote pills (1 min.) p.c. The stomach was washed out with sulphocarbolate of sodium (20 gr. to the pint of water). The patient was very much relieved and was ordered to continue the syphonage.

Digitized by Google

CASE 12.—The patient, a man aged thirty-two, was at the infirmary from March 30th to May 4th, 1895. He was placed on diet No. 2, with milk. There was a history of about six months' pain and vomiting, with wasting and anæmia. He vomited a pint or more at a time, usually in attacks lasting from two to three days and occurring about every fourteen days. Treatment: alkaline gentian mixture with nux vomica; syphonage with bicarbonate of soda. The patient obtained great relief and is continuing the treatment.

Remark by Dr. CURETON.—My thanks are due to the present house surgeon of the infirmary, Mr. Godson, and to his predecessor, Mr. MacLeod, for their kind help in collecting the notes of the above cases for my use.

Reviews and Notices of Books.

Essays in Heart and Lung Disease. By ARTHUR FOXWELL, M.A., M.D. Cantab., F.R.C.P., Physician to the Queen's Hospital, Birmingham. London: Charles Griffin and Co. 1895.

IN this volume the author has collected and revised some of the papers that he has, during the past decade, contributed to medical societies or to journals. They are obviously the outcome of much thought, and they deal with topics of high interest and importance to the clinical observer. The opening paper on Dyspnœa, for example, presents in clear and forcible language the varieties of this symptom of respiratory and cardiac disease comprising a discussion of the causation of the asthmatic paroxysm. The subject is illustrated by descriptions of cases in the experience of the author and the discussion of treatment. In the next paper, on the Expectoration in Phthisis—the term is here used to cover all forms of destructive lung disease—the subject is dealt with in each case under the three heads of (1) the nature of the expectoration; (2) the reasons for this nature; and (3) treatment. It is a useful systematic account of this common symptom. Under the head of "Catarrh" Dr. Foxwell opens up several novel and interesting questions. He is convinced of the utility of including under this head many local inflammatory affections other than those of the mucous membranes, and his arguments are worthy of all attention; but he further regards acute pneumonia and acute (primary) peritonitis as examples of "constitutional" diseases allied to the same group. He draws a striking contrast between the type of acute pneumonia in children as seen by him at Manchester and that seen at Birmingham, a kind of comparison which we do not remember to have been made before. Nor does it appear as if the difference is to be explained by regarding the one group as conforming more to the type of lobar pneumonia, and the other to that of lobular. In his essay on "catarrhus" he reviews the grounds upon which he has been brought to the conviction that these pyrexial disorders in which one or more organ or tissue of the body may be affected are in all probability due to the intervention of a microbe—perhaps the pneumococcus—and it is impossible to adopt this view without being reminded of influenza and its multifarious sequelæ. It seems only logical to take this step, and to refer all inflammatory states which are attributed to chill or to climatic and seasonal changes—to the operation of specific infection upon the predisposed organism. Indeed, if inflammation itself is only evoked by the intervention of microbes, then there is no escape from some such conclusion as that drawn by Dr. Foxwell from other data. How strange it is that teaching, which in one generation would appear to be fanciful and far-fetched, comes in the next generation to be regarded as the most rational and appropriate. It does, indeed, appear, without ignoring the admitted power of chill and exposure as leading factors in the etiology of catarrhal affections as if they should no longer be regarded the essential elements in their production. The volume includes three papers on climate, particularly of Davos, Arosa, and St. Moritz, which prove that the author made good use of his sojourn there, for he furnishes much information that is of value to those who have to advise pulmonary invalids as to their winter resort. Papers on the Condition of the Vascular System in Anæmic Debility and on Arterial High Tension are amongst the most interesting of these essays, which also deal with such subjects as Hæmoptysis, the Curability of Phthisis, and Non-tuberculous Cavities, the whole forming a volume that contains much that is reasonable and suggestive.

Edinburgh Hospital Reports. Published under the Editorial Committee of the Royal Infirmary, Royal Hospital for Sick Children, and Royal Maternity and Simpson Memorial Hospital. Edited by G. A. GIBSON, M.D., D.Sc.; C. W. CATHCART, M.A., M.B.; JOHN THOMSON, M.D.; and D. BERRY HART, M.D. Edinburgh and London: Young J. Pentland. 1895.

THIS volume is No. 3 of the series of reports consisting of, besides statistical tables drawn up by the registrar, papers and observations upon various medical and surgical subjects, the texts for which are furnished in the main by cases that have been admitted to the various institutions named on the title-page. Besides what we may call the purely professional and scientific papers there is an account of the new Craig House of the Royal Edinburgh Asylum, by Dr. T. S. Clouston; of the Deaconess Hospital, Edinburgh, by Dr. Gibson; and of the Victoria Dispensary for Consumption and Diseases of the Chest, by Dr. R. W. Philip. Altogether there are forty-two papers, but we have only space to mention a few of them. Dr. Wyllie contributes a long and interesting paper on Gastric Flatulence, dividing it into "true" and "false," according to whether the gas is produced in the stomach by fermentation or introduced from without, as in the case of patients who swallow air. In the former class of cases marsh gas and other carburetted hydrogens are sometimes formed, and Dr. Wyllie quotes an instance of a farm bailiff who happened to eructate at the moment he was lighting his pipe, when the gas caught fire, with a slight explosion. It is possible that cases like this may have been the foundation of the many stories of spontaneous combustion. The habit of air gulping, Dr. Wyllie says, is usually hysterical, though it may be a sign of obstruction somewhere in the alimentary tract. Dr. Byrom Bramwell gives details of twenty-three cases of myxœdema and five cases of sporadic cretinism treated by thyroid feeding, with most successful results. Photographs are given of the condition of patients before and after treatment. Dr. L. Bruce publishes an extended version of the papers contributed to our columns last year[1] on the value of thyroid feeding in some forms of insanity, and Dr. J. Macpherson has collected a number of instances where surgical interference was employed in cases of non-traumatic insanity. Headache, &c., were relieved, but there was not any very marked improvement in the mental condition. Dr. Gibson and Dr. Fleming have an interesting paper upon Characteristic Modes of Fatal Termination in Multiple Neuritis, and among the wealth of other papers we may mention that of Dr. Miles on Skin Grafting from the Lower Animals; Dr. W. Elder's Note on Aphasia; and Professor Annandale's Practical Hints upon the Operative Treatment of Cancer of the Lip, Face, Mouth, and Throat. Professor Chiene continues from Vol. II. his valuable Practical Observations in Surgery. Dr. Affleck writes on a Case of Beri-beri and Dr. A. Morison on the Blood Pressure in Angina Pectoris. A word of praise must be given to the printer and publisher for the excellent way in which the volume is got up.

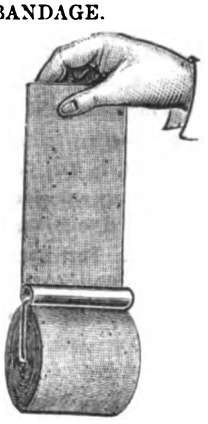
Mentally Deficient Children; their Treatment and Training. By G. E. SHUTTLEWORTH, B.A., M.D. H. K. Lewis. London. 1895.

IN this useful and practical manual the author sets forth, as the result of the experience gained during a period of twenty-five years' residence at Earlswood Asylum and the Royal Albert Asylum, Lancaster, the salient peculiarities of the class of imbeciles and the ameliorative measures found most useful.

The pathology of the subject is only touched on to supply practical hints to the medical man when consulted in the case of a mentally feeble or deficient child. Chapter I. contains a historical retrospect referring to the work of Séguin in France, Saegert in Berlin, and Guggenbühl in Switzerland simultaneously. A comparison is made between the accommodation provided for mentally defective children in other countries, especially in the United States, and that found in this country, the total provision here being at most for 2700 cases, while in the United States 6315 children are accommodated. Comparatively poor countries, like Denmark and Norway, appear to do much more for mentally defective children than we do in this country. Chapter II. refers to those less definite cases of mental infirmity which in later years have been described under the specific designation of "feeble-minded." The result of Dr. Warner's investigation into abnormalities in school children are given, and notice is taken of the establishment under the London School Board of "schools for special instruction" of children who cannot be properly taught by ordinary methods, "occupations" forming an important part of each day's work. In Chapter III. is given the pathological classification of forms of mental deficiency, the author grouping them as congenital, non-congenital, and developmental. There are good plates giving illustrations of cranial contours, pathological conditions, and types of idiocy. Chapter IV. is concerned with etiology, diagnosis, and prognosis of the different varieties. "Idiocy," "imbecility," and "mental feebleness" are shown to be merely grades of mental defect, and the occasional association of moral weakness with the latter is pointed out. In Chapter V. treatment is considered under the headings: (*a*) General, (*b*) Medical, and (*c*) Surgical. A plate shows crétin children before and after treatment with thyroid extract. The author is opposed to craniectomy for microcephalus, though in favour of cranial operations when mental deficiency is associated with traumatism, epilepsy, and paralysis. In Chapter VI. the important subject of Educational Training is considered under the heads: (*a*) Physical, and (*b*) Mental, the dictum of Séguin, "the physiological education of the senses must precede the psychical education of the mind," being insisted on; and the author points out the special methods of instruction needed for those who cannot "properly be taught in the ordinary standards or by ordinary methods." Illustrations are given of the simple apparatus used in training the senses. Chapter VII. treats of Industrial Training and Recreation. In Chapter VIII. the author urges the importance of moral training, and gives instances of the difficulty of dealing with moral imbeciles who have, perhaps, little intellectual deficiency. In Chapter IX. Results and Conclusions are given, the author quoting Dr. Fernald to the following effect: "It is safe to say that over 50 per cent. of the adults of the higher grade who have been under training from childhood are capable, under intelligent supervision, of doing a sufficient amount of work to pay for the actual cost of their support whether in an institution or at home." The author closes the chapter by repeating his views as to the need for further provision both for idiots and the "mentally feeble."

A copious bibliography is given in the Appendix, and very useful lists of school books, appliances, and speaking exercises suitable for special instruction of mentally-deficient children. In Appendix D is given a list of training institutions in Great Britain and Ireland for this class of patients.



LIBRARY TABLE.

A Guide to Hindustani specially designed for the use of Officers and Men serving in India, including Colloquial Phrases in Persian and Roman Character, and a Collection of Arzis, with Transliteration in Roman-Urdu and English Translations. By G. S. A. RANKING, B.A., M.D.Cantab., Surgeon-Lieutenant-Colonel, Indian Medical Service, &c. Calcutta: Thacker, Spink, and Co.; and 87, Newgate-street, London. 1895.—The nature of this work is set forth in its title, and we may add that it is what it pretends to be—viz., a really excellent book for acquiring a knowledge of the subject such as has not hitherto been available within the compass of a single volume. This is the third edition, and its author has added much that he had, for the sake of brevity, omitted in the former editions. It gives a concise and reliable grammar of Urdu, with a capital selection of military and medical phrases, translations of manuscript exercises, and passages for translation. It seems to us to be just the sort of book required for those for whom it has been specially designed.

A Medical and Surgical Help for Shipmasters and Officers in the Merchant Navy, including First Aid to the Wounded. By WM. JOHNSON SMITH, F.R.C.S., Principal Medical Officer, Seamen's Hospital, Greenwich. London: Chas. Griffin and Co., Limited, Exeter-street, Strand. 1895.—It is not by any means an easy task to write and compile a book on this subject which shall be sufficiently comprehensive, and at the same time sufficiently clear and practical as to be really useful to those for whom it is designed: but we think Mr. Johnson Smith may be congratulated on having accomplished his purpose. We have applied to this book the test of looking through it generally and of specially referring to several portions of the volume treating of various subjects with a very satisfactory result. The work is illustrated with coloured plates and numerous engravings, and the instructions given—whether in relation to the treatment of disease and injury occurring on shipboard under circumstances where specially skilled assistance is not available, or in dealing with the prevention of disease and the feeding and nursing of individuals suffering from infectious fevers and internal affections—strike us as sound and judicious, and really helpful under the circumstances. The author, in order to make his treatise as complete and useful as possible, has availed himself of all the latest information, and also of the suggestions of the medical officer of health for the Port of London and others, and has added a chapter on cooking on shipboard for healthy men and invalids, specially prepared for the work by the instructor in nautical cookery to the Wells-street Sailors' Home.

New Inventions.

THE "NON-RUN-AWAY" BANDAGE.

HAVING experienced the inconvenience and loss of time occasioned by a bandage falling from the hand and unwinding, I have suggested to Messrs. Reynolds and Branson of Leeds a simple plan for holding the same. The illustration will explain the idea, which will, I trust, be found in practice to supply a want long felt by house surgeons and hospital dressers. Should only a part of a six-yard bandage be employed for a dressing, the remainder will be left securely rolled for future use.

THE LANCET.

LONDON: SATURDAY, AUGUST 24, 1895.

THERE are some broad principles to be remembered in considering the best way of meeting the demand for greater stringency in maintaining the ethical standards which have hitherto been supposed to govern the profession. This demand is very general, and comes very creditably from the great body of general practitioners. It is too common to speak as if errors of behaviour were confined to this section of the profession, and as if in the ranks of consulting practice there were no doubtful methods of success. We are under no such delusion. There are the same circumstances of pressure and competition and the same weaknesses of character in the one sphere of practice as in the other. Certainly, as we have said, the demand for greater stringency comes very much from the rank and file of the profession. The proceedings of the recent meeting of the British Medical Association prove this. Some great authority with strong powers to be used somewhat vigorously is demanded, that can at once protect the public against the experiments of false pretenders and unqualified practitioners and the profession from the discredit of men within its pale who lower its dignity and ignore its traditions. The long series of resolutions passed at the recent meetings has this significance.

The question is, In what body is this power of discipline to reside? and to what extent is it necessary to appeal to Parliament at all? Parliament is well known to be reluctant to undertake medical legislation, and those who have seen most of the haphazard way in which medical legislation is eventually effected will be most ready to admit that before we do appeal to Parliament we should be clear on two points—first, that the profession has done all it can do by the use of its own influence, its own immanent power, and the exercise of its present legal rights. The second point on which we should be clear is as to the exact defect in our present powers, and the form in which we should approach Parliament with a view to legislation which would supply that defect. It is not ten years since Parliament passed a great Medical Act, conceding amongst other things the principle of direct representation. It is rather early to expect a Government to reopen the subject unless a very good case is made out for so doing, not only in the interests of the profession, but in those of the public. Many of the evils from which the profession itself is now suffering—as, for example, low and unworthy methods of practice, such as demean it in the eyes of the public and are, indeed, inconsistent with the proper treatment of disease—should be met, in the first instance at least, by the action of the voluntary associations of the profession. Law should never be asked to do that which men can and ought to do for themselves. Parliament does not give privileges and protection for nothing. It is pretty sure to impose conditions which rob the concession of much of its value. Let us then do what we can for ourselves as members of a profession, liberal indeed, but yet a profession conscious of its own dignity, of its rights and its responsibilities. There are some big questions which voluntary action should settle without appeal to Parliament or even to the medical authorities. Take, for example, the questions of medical aid associations, cheap dispensaries, wholesale contempt for the sanctity of medical service. Surely medical men in local societies, as that of Cork, or in the British Medical Association, by firm and united action can make their influence felt effectively. By remonstrance, and, if need be, by excommunication, they can make the offender ashamed of himself and bring him to recognise that he has duties to his profession as well as to himself which he cannot ignore without losing caste. A very striking example of what can be done in this direction is afforded by "The Battle of the Clubs at Brussels," an account of which by our Special Commissioner will be found in our present issue. It is not to be expected that Parliament will assign penal or disciplinary duties to voluntary associations of medical men, however large or powerful. They have their own powers and their own influence, which have never yet been fully or systematically used. But there are many indications that such associations as already exist will have to use their powers for ethical and disciplinary purposes much more seriously if they are to retain the respect of their members and of the public itself, which, after all, respects the profession the more when it shows that it respects itself.

Further, in contemplating the acquisition of more stringent legal powers of discipline for the profession we must not forget that Parliament or Royal Charters have already fixed the seat of these powers in two clearly defined quarters—the medical bodies, or, as they are called in the Medical Acts, the medical authorities, and the General Medical Council. It is by no mere accident that these powers have been placed where they are. The bodies which give diplomas to candidates impose the conditions by which these diplomas are held. Amongst these conditions are character, conduct, respect for by-laws. In the sister profession of law provisions for such conditions are more stringent, yet they are not more essential than in medicine. It is proper and natural that these bodies should have any additional powers needed to give efficacy to their disciplinary functions. Above and over all these is the ethical function of the General Medical Council. But this should rarely be called into exercise—first, because it is costly and cumbrous in its action, and, secondly, because it is fit and proper that the body which has assumed the responsibility of giving qualifications to man should be the first body to remonstrate with him and, if need be, punish him if he errs from the line of professional conduct. In any amendments of the Medical Acts, therefore, the great demand of the profession should be based on the existing facts and functions of the medical bodies and the General Medical Council, and power should be given to the General Medical Council to notice errors of conduct that, short of being "infamous," may be discreditable, or disgraceful, and thus injurious to the profession and the public.

THE office of coroner is one of the most important of our English institutions, as it is one of the most ancient. Our

Digitized by Google

views on the paramount urgency of maintaining its importance, so that all inquiry into unexplained deaths shall be carried on with the dignity, thoroughness, and formality that are fitting, are so well known that we need not repeat them; but it is, we hope, apparent to all our readers that it is because (and only because) we set such a high value upon the coroner's functions that we have been in the habit of watching jealously over the administration of "crowner's quest justice" and of allowing ourselves to comment freely upon anomalies or shortcomings that from time to time are brought under our observation.

A story has reached us this week from Bradford to which it is our duty to give prominence, for the essential point of it is—if we are correctly informed—that a member of our profession has incurred an outspoken expression of dissatisfaction from a coroner's jury for recognising the value of medical services, and refusing to prostitute them to the convenience of those interested. The story is as follows:—On the Saturday before Bank Holiday the wife of a labourer residing in Bradford went to Morecambe, and returned on the following Monday very ill. She died early on the ensuing Saturday morning after being ill all the week. On the night before she died a medical man, Mr. W. J. MARSH of Bradford, was sent for. He saw her and prescribed for her; but, whatever the chances might have been in her favour had medical attendance been summoned sooner, it was then too late for effectual treatment, and the next morning she died. Mr. MARSH was then asked by the husband for a certificate of death. This he said it was impossible for him to give, as he only saw the woman on the previous day, and he did not feel prepared to certify to the cause of death. It would have seemed to us impossible to find fault with conduct of such undeniable prudence had it not been brought to our notice that, for refusing to give this certificate, a coroner's jury has formally registered its dissatisfaction with Mr. MARSH, while the coroner has made the incident a peg whereon to hang a remark that certainly was not meant to be polite, and might bear the interpretation that greed for fees was at the bottom of the refusal. At the inquest the coroner told the jury that they would not have been troubled with the case but for the refusal of the medical man to give a certificate. The jury suggested that the medical man should be present. The coroner is then reported by the *Bradford Evening Telegraph* to have said: "I will, if you wish, send for the doctor to explain, but I shall not pay him a guinea for coming. What do you say, gentlemen? Are you satisfied with the evidence, or do you wish to see a doctor?" To this the foreman of the jury is reported to have replied, "We are satisfied with the evidence, but dissatisfied with the doctor." We cannot exactly apportion the blame of these words between the foreman and the coroner. The foreman spoke them, but they seem to be a very natural outcome of the coroner's preceding speech, and we desire to join issue with them at once by saying that we are satisfied with the medical practitioner and dissatisfied with the attitude assumed towards him by the court and the jury. The medical man in attendance upon a patient is the only person who can possibly judge whether he is justified in giving a certificate of the cause of death or no, and if medical men should be frightened into giving death certificates when they are uncertain of the cause of death we need hardly point out that one of the chief safeguards against secret murder is lost to society. That is what such treatment as Mr. MARSH has experienced may quite easily bring about. To avoid trouble and to be safe from impertinence certificates might be given without proper regard for their accuracy, and the persons who will benefit by the amiable innovation are the WILLIAM PALMERS and NEILL CREAMS of the future.

No one but a medical man can say if the cause of a particular death is apparent or not. In this case the medical man elected to say that it was not apparent. This does not mean that there was necessarily anything obscure about the case, but simply that opportunities had not been forthcoming for the medical man to discover the cause. And upon the distinct lead of the coroner the jury expressed their public dissatisfaction with the medical man for exercising rightful caution—caution which, if left unexercised, would subject the medical man to the rightful censure of law and society. The words of the coroner that he would not send for the medical man, or at any rate would not pay him a guinea for attending, amount to an insinuation, if not exactly a charge, against Mr. MARSH that he withheld the certificate so as to be summoned and receive a guinea. But on this point we will quote Mr. MARSH'S own words, addressed to the *Bradford Daily Telegraph* of Aug. 14th, after being assured that the coroner's words had been correctly reported: "I gave the relatives of the deceased a written statement of the very little I knew of the case, thinking that possibly it might help to satisfy the coroner that a formal inquest was unnecessary. Also, by way of anticipating any possible attempt at malicious misrepresentation, I will make a clean breast of the enormity that I told the relatives that if this statement should have the desired effect of saving them from the annoyance of an inquest, I should expect them to pay me for it out of the insurance money, but that, recognising their poverty, I would be satisfied with a modest 2*s*. 6*d*. in addition to the still more modest 1*s*. 6*d*. which they had already paid me. I appeal to the relatives whether they did not express their obligation to me for my kindness and moderation? These remarks are my answer to the coroner's oblique suggestion that I was hankering after a dirty guinea." We have nothing to add. There will be found in our correspondence columns this week an answer to a medical man who had inquired as to the amount of facility that it was his duty to give to a coroner without being summoned. His language is very plain, and amounts to this—No guinea, no opinion. Within certain limits we endorse that view. It is no duty of the medical man to give to the coroner the assistance that expert medical knowledge can generally supply in the search for the cause of death save in return for a fee. In addition to this, preliminary and casual conversation on such an important matter as the exact cause of a death requiring or seeming to require an inquest is unsafe. Whatever scientific facts or views the medical man may desire to make public should be made public upon oath. But this does not preclude the

Digitized by Google

medical man from helping the coroner should he be asked as to the lines upon which the inquiry should run; and often, when the coroner is a layman, such assistance is, as we know, highly valued. But while we recommend every courtesy and liberality to the coroner, because of the high importance of his office, we cannot but see that there are certain coroners who desire to exclude medical evidence from their courts, and who attribute to the medical witness pecuniary greed on the smallest provocation. While this is so we cannot expect medical men to do other than stand on their strict rights.

THE condition of London generally, but more especially of the East-end, in respect to water-supply is a matter of urgent importance. It has been fully demonstrated that the water-supply can only be relied upon in normal seasons. We now know that the pipes will burst and the water fail to reach a great number of houses if there is an abnormal frost; and that, in the East-end at least, there is not under actual circumstances water enough for a constant supply during an exceptional drought. What we do not know is when an exceptional frost or an exceptional drought may again occur. We cannot tell how soon we may once more have to endure all the dangerous inconvenience which has been experienced during the past winter and the present summer. Under such circumstances the water-supply as at present organised stands condemned. The only debatable question is how it can best be altered and improved. So far as the East-end is concerned, the facts are so peculiar that they suggest that the present water famine was due as much to mismanagement as to the drought. We are assured that when the constant service was reduced to three hours per day the supply in East London was equal to 30 gallons per day per head. This is a good supply. It is, in any case, better than the Birmingham supply, which is equal to 25·5 gallons; while Manchester has only 24 gallons. It seems evident that great waste must have occurred somewhere, for with a supply of 30 gallons per head per day there should be no more complaint in East London than there is in Manchester, Birmingham, and many other towns. Now we are told by the East London Water Company that the average amount of water pumped in May was 51,000,000 gallons per day, which was equal to 42 gallons per head; that the supply had begun to run short from May 27th; and that in June the constant supply was cut off during several hours of the night, with the result of an economy of 10,000,000 gallons per day. This would imply that about a fifth of the consumption takes place during the night, a suggestion which does not seem credible. These figures represent, we should imagine, waste rather than consumption. Some of this waste was undoubtedly due to the carelessness of the inhabitants, who allowed their taps to run all night, but could such carelessness account for 10,000,000 gallons? This seems doubtful. Mr. BINNIE, engineer of the London County Council, attributes the waste to the leaking condition of the pipes fractured by the hard frost of last winter. In confirmation of this theory we find that, in answer to complaints as to the dirty condition of some of the water, it was urged that the water on leaving the filtering beds was perfectly clean. Then it is said that the water must have been fouled while in the pipes; but how could such an occurrence take place if the pipes did not leak? If the leakage was sufficient for the dirt to enter when the pipes were not under pressure, water must have escaped from the pipes when they were under pressure. Thus the thirty gallons per head supplied daily probably never reached their destination, but a notable proportion was lost by leakage and wasted in the subsoil.

From the public health point of view it is first necessary to solve the question of the probable leakage of the pipes. An outcry is now raised against the constant supply system. Everyone admits that sanitarians are right when they insist that constant supply is the only really safe system. On the other hand, it is maintained that what is theoretically right has been proved, by the trouble in the East-end, to be impracticable. Such an argument, we would urge, is altogether premature, for before it can be considered of any value it must be shown that the pipes did not leak. Nor should we be inclined to give up the constant supply system even if it were conclusively established that the pipes are sound. All that could be said, is that the system was badly applied. Before abandoning the constant supply system and reverting to the oft-condemned methods of house storage, to the domestic cisterns which are so easily fouled, and in which the purest water becomes tainted, we would first seek better means for preventing waste. Taps, we are told, are left open and the water allowed to run to waste. But surely, with the exercise of a little ingenuity, some means could be devised to prevent this loss of water. To begin with, all taps should be spring taps that close automatically and can only be held open by force. It is true that where there is a handle it can be held back by a string or a wedge; in that case the tap would not be left open through carelessness, but with malice prepense. As a great proportion of these taps are in backyards and courts, they are easy to inspect, and persons guilty of such malicious waste could be prosecuted. Then there is another form of tap which has no handle that can be tied, but only a small button that must be pressed against a strong spring. It must be remembered that a danger exists in the use of spring taps on a high-pressure system. If the tap is suddenly shut a shock is communicated by the column of water which may easily split the pipes. This danger, however, can be obviated by having a pipe with a reduced bore between the tap and the main—that is, in the case of a direct supply. These and many other devices must be tried, and fully tried, before the proposal to revert to intermittent supply and dangerous domestic cisterns can be entertained.

Of course, we admit that this latter and oft-condemned system is infinitely preferable to a complete stoppage of water-supply, such as that which many inhabitants of London have just experienced. It is true that the outbreak of small-pox is not to be ascribed to this cause, but in all probability the increased prevalence of diarrhœa may be attributed to some extent to the deficient water-supply. Concerning the small-pox, we consider that the growing neglect with regard to the enforcement of vaccination is more likely to supply the correct explanation of the actual state of affairs. Fortunately, Mr. CHAPLIN and the present Government are entirely independent of all the so-called faddists. The delay in the publication of the report of the Royal Commission on

Digitized by Google

Vaccination is no excuse for neglect in the application of the Vaccination Acts. If some of the boards of guardians are remiss in the fulfilment of their duty in this respect, the present Government has power enough to so alter the law on vaccination that its application shall be entrusted to the Local Government Board. If, with the more strict enforcement of vaccination, such places as the Salvation Army shelters were brought under the Common Lodging-houses Act, the danger of a small-pox epidemic would be reduced to a minimum. These are, however, matters that stand apart from the question of water-supply, and we mention them only to show that care must be taken not to confuse two totally different issues. To return to the water famine, we repeat that many measures must be taken before any thought of abolishing the constant supply system can be entertained. First the water mains and all the pipes must be proved to be sound. Then better taps must be employed, and better surveillance exercised to prevent waste in private dwellings. Finally, the amount of water at the disposal of the water companies must—and, we understand, will—at an early date be considerably increased.

Annotations.

"Ne quid nimis."

DEATH OF DR. BRISTOWE.

IT is with much regret that we have to announce the death of Dr. John Syer Bristowe, which took place at Dixton Vicarage, Monmouth, on Tuesday, Aug. 20th. Dr. Bristowe had been for many years a prominent figure in London medical and scientific circles. He was the senior consulting physician to St. Thomas's Hospital, and had filled, among many other posts, the offices of President of the Medical Society, President of the Pathological Society, and President of the Neurological Society. He was not a voluminous writer, but his "Theory and Practice of Medicine" is a classic. He was a frequent contributor to our columns, and also wrote the articles in Reynolds' Medicine on Pyæmia and Diseases of the Intestines. He was a most admirable clinical teacher, and his memory will ever be held in high honour at St. Thomas's Hospital which he had served so faithfully for many years. The funeral takes place to-day (Saturday) at Norwood Cemetery at 1 P.M. We shall publish an extended obituary notice in an early issue.

THE OPENING ADDRESSES AT THE MEDICAL SCHOOLS.

THE time is rapidly approaching when those who contemplate entering the medical profession will have to decide, if they have not already done so, as to the school where they will receive their training. On Sept. 7th, in accordance with our usual custom, we shall publish "The Students' Number" of THE LANCET, and intending students and their parents or guardians will find full information regarding the advantages offered by the various schools as well as other matter of pressing interest to the student. Most of the metropolitan and provincial schools will open either on Oct. 1st or 2nd, while many of the Irish and Scotch schools will not commence their winter terms till some weeks later. At a large proportion of the schools the opening is characterised by an introductory address, and the names of many of the speakers will assure the quality of the addresses. At St. Thomas's Hospital Sir Edwin Arnold will address the students, and he who has so ably dealt with the work of two of the greatest physicians of the soul the world has ever seen will surely be able to stimulate his hearers to work nobly in that profession whose mission is to heal the body. At Middlesex Hospital Dr. W. Julius Mickle is to deliver the address, at St. Mary's Hospital Mr. A. P. Laurie, at Westminster Hospital Dr. Monckton Copeman, at St. George's Hospital Mr. George D. Pollock, at University College Professor J. Rose Bradford, and at Guy's Hospital Mr. George De'Ath, who will take for his subject "Our Profession, our Patients, our Public, and our Press." University College, Liverpool, and the Sheffield School of Medicine are to be congratulated on securing Mr. Hutchinson and Mr. Horsley respectively as the deliverers of the opening addresses. Professor Percy F. Frankland will take for his subject at Mason College, Birmingham, "Pasteur and his Work: the Debt of Medicine to Chemistry," and Professor F. H. Napier will address the students of St. Mungo's College, Glasgow. Professor Penberthy will deliver the introductory address at the Royal Veterinary College.

THE EXPLOITATION OF INFANCY.

THIS is a burning question in Italy. So disastrous are the results of impressing children of tender years into industrial service, that some time ago a law was passed by the Chamber of Deputies limiting the age at which boys or girls could be so employed. Severe penalties were imposed on any mill or factory owner who had engaged "hands" of either sex under twelve years. This was hailed as an immense boon to the best interests of "young Italy," but after the first enthusiasm on its enactment the law came to be quickly and systematically ignored, till the rising generation of Italians are demonstrating all too indisputably, in deteriorated physique and premature senility, that the springs of life have been drained at their source, and that persistence in this criminal breach of a wise regulation will have calamitous consequences for the future of the kingdom. Signor de Andreis, a philanthropic deputy, in a recent discourse on the subject, declared that the whole series of enactments for the protection of the child and the female against industrial employment unsuited to age or sex was in Italy so utterly set at naught that the very judges before whom a case of infringement of the law in question happened to come expressed astonishment that anyone should appeal to them for redress. The returns of the inspecting officers of the Italian army medical department speak with an eloquence all their own of the need for a stringent enforcement of the law. The augmentation of the maladies, the deformations, the stunted growth or impaired development which necessitate the rejection of the conscript has of late years become simply appalling. In the "circondario" (district) of Milan alone within the year now passing, out of 6844 youths enrolled for the levy more than 45 per cent. were found too infirm or too malformed to complete the term of military service. *Pari passu* with this physical deterioration proceeds the moral, as shown in the saddening statistics of penitentiaries, houses of correction, and prisons, all full of premature "failures or worse" in the battle of life. At the age when the budding child ought to be at school, undergoing salutary discipline, mental and bodily, he is plunged into the pernicious atmosphere of the factory or the industrial "hive," there to be initiated in all the seductions, temptations, and vices, often ending in crimes, of which these aggregations of "hands" are all too prolific. Nor is it Italy alone that suffers from this sapping of her national vitality at its source. As the International Congress for the Protection of Infancy at Bordeaux has just indicated, there is no country in Europe which has not to

Digitized by Google

revise its *modus operandi* in the upbringing of its tender youth. But Italy's grinding poverty is an exceptional feature in her case, at once aggravating the evil and complicating the machinery for remedying it. Not a day too soon, therefore, do we hear of a steadfast attempt to be made in the next session of her Parliament to secure the observance of a salutary but shamefully violated law, and to devise other measures for the extension to the children of those conditions, hygienic and educational, without which no people can "live and thrive" or play its normal part in the world.

DEATH FROM ICE-CREAMS.

IT is well known to everyone who has worked in a hospital that there are seasonal casualties and accidents as well as seasonal diseases. Thus the boiling kettle and fire accidents occur more commonly in winter, while street accidents among children at least are of more frequent occurrence in the summer owing to the children being out more. The ice-cream season, too, claims its victims, and every year one or more deaths are registered from this cause. The cream, of course, must be held blameless, for this ingredient occurs in such small proportions that we may neglect it. It is probable that the chief offenders in the formation of poisons are the eggs, and that, as in the case recently reported from Limerick,[1] eggs which are not exactly putrid, but have undergone some change, probably owing to a micro-organism, are the cause of the alarming symptoms which sometimes arise from eating these confections. At an inquest held on Aug. 14th upon a youth aged nineteen evidence was given that he used to spend as much as 5*s.* to 7*s.* 6*d.* at a time upon ice-creams and sweets, which he devoured greedily. He died from acute gastro-enteritis. The sanitary conditions under which these ice-creams are made in many instances leave much to be desired, and we must continue to advise, as we have already done,[2] an extension of the Factory Act so that private houses in which manufactures involving public interests are carried on should be duly inspected by a public official. We should be extremely sorry to eat 7*s.* 6*d.* worth of good ice-cream, and perhaps the quantity which the unfortunate youth devoured may have had something to do with his death as well as the quality.

MOUNTAINEERING IN MIDDLE AGE.

THE holiday season, though well advanced, holds out, with a promise of late summer weather, the hope of leisure and recreation rendered all the more attractive by being deferred. Suggestions where to go and what to do are not yet exhausted. Sea and land everywhere have a welcome for the tourist who comes with no other object than to seek refreshment in the house of nature. Among other proposals we select one as being to some persons particularly fascinating, and affording at the same time an occasion for medical criticism—that, namely, which advises mountain climbing as a pastime for the middle-aged. The originator of this project, whose letter on the subject our readers may have seen, is "a superannuated climber." This description of himself is important. It is on the one hand a guarantee of his experience in the task he advises, and it affords on the other an explanation of his personal fitness to accomplish it with enjoyment and benefit. The Tatry Mountains in Austro-Hungary are described by him as being under 9000 ft. in height, bathed in air of the finest purity, peopled by hospitable inhabitants who provide excellent food and quarters, and traversed by guides whose civility and other good qualities are warmly commended. Those whom nature or the incapacity due to habit or bodily condition have not disqualified may well be content to enjoy such an athletic holiday as this. It is well, however, to bear in mind the fact that middle age in itself does not constitute a qualification. The practised climber or walker may often live safely according to his custom till threescore years or after. His brother and *alter ego* of sedentary occupation must regard the claims of stiffened joints and sinews long before that period has arrived. Not a few hearts and bloodvessels, moreover, have felt the strain of life before even fifty years of it have passed. For them the steep ascent, the rapid blood-flow, and quick breathing imply rather another and serious form of overstrain than a wholesome gymnastic competition of their organs. We touched upon this subject a few weeks ago[1] and we need not, therefore, discuss it now at greater length. The question of fitness or unfitness is, in short, a matter for individual decision, and we know of one method only by which it can be settled—namely, by medical examination.

CHILDREN'S AILMENTS AND HOUSEHOLD PREVENTIVES.

SOME ailments of children are like a simple mechanical puzzle—obscure, complicated, alarming in their symptoms, very troublesome if mismanaged, but in their cause and explanation simplicity itself. Last week a boy was taken ill from the effects, as was supposed, of a heavy dinner. Thanks to the guiding symptom of pain the true seat of his disorder was quickly discovered, and the rectum was found to be tightly packed with the broken but unmasticated fragments of nuts, a meal of which he had recently consumed on his own account. An anæsthetic and forceps relieved him of his load, the more usual means having failed to do so. A mouth full of decayed teeth showed how, in his case, mastication was well-nigh impossible. The danger of allowing so much rough and hard matter in a state quite incapable of digestion to traverse the length of the intestinal tract, or to become impacted at some point in it, is such as even an unprofessional mind can appreciate. This case, unique perhaps in actual particulars, is one of many, some of them as clear, and some obscure in character, but all capable of much mischief and misunderstanding, which bear one common accusation—indiscretion in diet. Now it is a poisonous ice-cream, now a stale fruit, now a mass of broken nuts. The inevitable question arises—Who is responsible? And its answer will usually acquit the salesman if he be a careful and fair dealer. Child and parent, therefore, must divide the blame, if any, and of the two the more intelligent will naturally have the larger share. Such cases as that above quoted should at all events impress upon parents the lesson, too little regarded, that failure to warn, and to prevent if needful by active measures, the heedless indiscretions of, their children may at any time induce, perhaps by very simple means, an illness of the greatest gravity.

A GERMAN SCHOOL OF COOKERY.

VOLTAIRE said that the English people had 100 religions (according to Whitaker's Almanack we now have about 250) and only one sauce. This, of course, was merely national jealousy; but the fact remains that English cookery is not in general good, and the knowledge of this art among the labouring classes is practically *nil*. Their *batterie de cuisine* consists of a frying-pan, in which they never "fry" but "do" things. Take the upper classes, again—in how many houses does the diner-out get an eatable curry, an omelette that does not resemble the sole of a boot, or coffee that has any right to that name? In Germany an admirable institution exists. A philanthropic millionaire left (according to the *St. James's Gazette*) a legacy to build and endow a school which is to be a model for the State schools of the country.

[1] THE LANCET, July 30th, 1895.

Digitized by Google

It consists of two houses, one for the children of the upper classes and one for those of the labouring classes. In the cookery school they have to settle themselves what is to be cooked each day and how much they will spend.

"To aid them in their selection and choice of comestibles a list is hung up on the wall, whereon the exact amount of nourishment each food substance contains is carefully explained—for instance, how much 'good nourishment' there is in meat, flour, vegetables, groceries respectively; and on this list it is also clearly shown on good scientific principles how much of each nourishing substance every individual requires per diem. After consulting this chart and making their little list of requirements and liabilities, the girls go out into the garden and gather the herbs and vegetables, which they are taught to cultivate themselves, and then they go and buy the meat, groceries, &c., from a lady superintendent at the store-room. The girls are taught to enter all these various items of their expenditure in carefully kept account-books, and then they start their cooking operations: one makes the fire while another prepares the vegetables &c. In two hours everything must be finished and the little dinner ready. They cook it themselves."

Then they have to "wash up," and afterwards they go home. We believe the School Board teach cookery, but we doubt if their course is as thorough as the German one, and we would adjure our English millionaires to follow the example set by their foreign brother in the possession of this world's goods.

THE HEALTH OF THE POPE.

OUR Rome Correspondent writes:—"The *al fresco* life His Holiness leads in the beautiful demesne between the Vatican Palace and the Janiculan[1] has told favourably on his health, which, all things considered, was never better than to-day. For one thing, he has no threatening of those fainting fits (*deliqui*) which, in the spring months especially and during the exigencies of urgent business, were apt to overtake him. With due allowance for the *anæmia senilis*, of which he has more than the average octogenarian's share, this result is of very good omen. The Commendatore Dr. Lapponi, *archiatro* to His Holiness, in reply to an interrogatory addressed to him the other day, felt warranted in saying: 'If nothing unforeseen happens, the Holy Father's constitution is so sound that he might well attain his hundredth year.' No one is more familiar with that constitution, I may add, than Dr. Lapponi, who was Leo XIII.'s medical adviser as far back as the days when he was Cardinal Archbishop of Perugia. The moment His Eminence became supreme pontiff he would have no other body-physician than Dr. Lapponi, and certainly the measure of health he has enjoyed under a mental and even physical strain that would have tested the vitality of far younger men says much for the judgment and care with which his health is safeguarded. Besides following scrupulously Dr. Lapponi's prescriptions, Leo XIII. observes the simplest diet compatible with effective sustenance. 'Little at a time and often' is his rule, his principal meal consisting of a cup of strong soup, a slice of boiled beef with a yolk of egg, and a wineglassful of Bordeaux or well-matured Marsala. Truly a commendable example of 'plain living and high thinking.'"

STREET NUISANCES.

IN the *Times* of Aug. 20th is a letter from Mr. C. S. Loch, the secretary of the Charity Organisation Society. We commend this letter to everyone who is interested in the cause of charity. The Hospital Saturday street collection was bad enough, but of late an innumerable number of societies have started street collections, and when the craze was in full swing, as it was about two months ago, to walk down Piccadilly or the Strand was a positive penance. At every step a siren or harpy—we will not be too careful to discriminate—appealed for pence "for the little ones" or "the destitute washerwomen" or "the young Bethelites' country holiday fund." We have no doubt that the pennies of the charitable reached their due destination, but what we complain of in this method of collection is that there is no guarantee to the effect that the money is properly applied. In the Hospital Saturday Fund street collection this objection, of course, does not apply, but we fancy we are right in saying that the street collection of the Saturday Fund has fallen off by about £1900—and this result is probably owing to the disgust of street collections which the numberless imitations have inspired. Mr. Loch says we must trust to persuasion rather than legal action; but, in our opinion, if the officials responsible for the sending out these beggars—if, indeed, there are any officials—and, if not, the beggars themselves, were punished under the Vagrancy Acts, something would be done to make the streets a little less odious than they are at present. Organs, newspaper boys who yell, street-sellers of toys that whistle or squeak—all ought to be suppressed as well. The charitable beggar is, however, in some way the most offensive of the lot, and we can only rejoice that by this very multiplication he seems to be tending towards extinction.

[1] THE LANCET, July 13th, p. 128.

HOSPITAL PATIENTS IN VIENNA.

THE attendance of comparatively well-to-do persons in the out-patient rooms of the various London hospitals has long been a subject of complaint. Both general practitioners and the opponents of indiscriminate charity have lifted up their voice against the evil, the reality and magnitude of which are unquestionable, but no adequate or satisfactory method of dealing with it has yet been put into practical operation. The same question has for some years been engaging the attention of the medical profession in Vienna, and according to our correspondent in that city there is a prospect of united action being taken in the matter. The Vienna practitioners complain that not only do persons well able to afford the usual fees attend the out-patients' department of hospitals, but they become paying in-patients at charges so low as to be unremunerative to the institutions, the deficiency being supplied out of the grants provided by the State. In many cases, however, such in-patients when suffering from surgical ailments are influenced by the fact that antiseptic operations cannot be performed in ordinary lodgings. The medical men of the present day are as ready as any of their predecessors to relieve the really necessitous, but it is felt that there is a growing tendency on the part of the general public to seek low-priced medical advice, a state of things which is injurious to the true interests of all parties concerned. With a view to solve the problem, our Vienna colleagues propose that only those patients who can show proof of straitened circumstances shall be entitled either to gratuitous medical aid or to hospital treatment at reduced scales of payment. If the idea reaches the practical stage the results of the experiment will be watched with keen and general interest.

MISLEADING ABBREVIATIONS OF DEGREES AND DIPLOMAS.

IT is not proposed to discuss here in any way whether or not it is desirable that medical men should place after the letters denoting their degrees and diplomas the university or examining board from which such degrees and diplomas were obtained. This question is one which must, we fear, be determined in large part by the exigencies of time and place. What, however, we would briefly refer to is the necessity, or, at any rate, the desirability, of adopting in

Digitized by Google

toto one course or the other. Half measures in this matter are apt to be misleading, and it is not consistent with the dignity of our profession to adopt methods which may be open to this criticism. The introduction of Diplomas in Public Health has apparently been instrumental in giving prominence to the methods of indication to which reference is here made. For instance, it is by no means uncommon at the present time to notice after a medical man's signature the letters M.D., D.P.H. Cantab., an arrangement from which the justifiable inference is, we submit, that both the degree of Doctor of Medicine and the Diploma of Public Health were procured at the University of Cambridge. In some cases, however, it would seem that the arrangement of the titles does not justify the interpretation which should obviously be placed upon them, and the M.D. degree may even be of exotic origin. It is not altogether clear why the source of a Diploma of Public Health should be specifically stated while that of a degree of Doctor of Medicine remains obscure; indeed, if the general contention be that the public should be educated in the matter of degrees, &c., it would appear to be of more importance that a medical practitioner should be selected on the merits of his M.D. than upon those of his D.P.H. We are not raising the issue of the relative merits of degrees and diplomas, but we would point out that on general ethical grounds it is desirable that if the origin of one degree or diploma is specifically indicated, that of the other should be so too.

THE HYGIENIC ASPECT OF WOOD PAVEMENT.

MR. WYNTER BLYTH embodies in his last quarterly summary of the health of St. Marylebone a report on the above subject. It is, he observes, to be regretted that the several sanitary authorities in the metropolis have not during recent years kept records of the health of those of their employés who have worked on the roadways of their districts, in order that some statistical basis might be formed from which conclusions might in time be drawn. In the absence of any such data, Mr. Blyth has endeavoured to contribute something to the knowledge of the subject by ascertaining experimentally whether the wooden blocks are saturated throughout with horse excreta, &c., or whether this pollution is superficial only. Taking as an index the amount of ammonia present in the upper, middle, and lower slices of blocks which had been laid down in Oxford-street for the last six years, and controlling his results by some of a new block of the same material, Mr. Blyth was able to demonstrate that in a block taken from the centre of the road the greatest pollution was found in the upper slice, although the block was as a whole permeated with pollution. In the case, however, of a block taken from the side of the road by far the greatest amount of pollution was found in the lowest slice, and in an amount much in excess of the block taken from the middle of the road. Mr. Blyth infers from this that the wooden blocks are by no means impervious, and that in process of time they become more or less saturated with impurity. The distribution, too, of the ammonia points, it seems, to the fact that the moisture tends to penetrate the intervals between the blocks in the middle of the roadway, and on reaching the impermeable bedding below tends to pass down to the sides of the roadway, and in this way to saturate the lowermost layer of the side blocks. Mr. Blyth, in conclusion, considers that for the purposes of health asphalt is the best form of pavement, since it, in all probability, is proof against the amount of saturation which he has demonstrated in wood. He recognises, however, the very trying noise which the contact of horses' hoofs with asphalt produces, and in summing up the effect of any one pavement upon health this feature should certainly not be disregarded. Mr. Blyth, it seems, looks forward to the disappearance of our horse traffic from our streets, and to the substitution of vehicles propelled by other motive power. It will not then, he observes, be necessary to consider the pit-pat of the horses' hoofs upon the asphalt; nor, we would add, the pollution of wood pavement by equine excreta.

DEATH CERTIFICATES AND THE RECOMMENDATIONS OF THE SELECT COMMITTEE OF THE HOUSE OF COMMONS.

IN an interesting paper read at the Medical Institution of Liverpool last March Mr. F. W. Lowndes, surgeon to the Liverpool police, discussed the very important question of what we may call irregular death certificates. In 1894 a Select Committee of the House of Commons was appointed to consider the whole question of death certification. The Committee made a number of recommendations, by far the most important of which was that the practitioner should be bound to verify the fact of death, either personally or by means of a certificate to that effect signed by two neighbours of the deceased. As the law stands at present, no verification of the fact of death is necessary, the practitioner being entitled to say, "A B died, as I am informed." This Mr. Lowndes rightly considers a very grave defect. He also lays stress upon the fact that in some cases a practitioner who has only seen the patient after death has considered that to be "attendance" and has accordingly filled up the certificate. Mr. Lowndes suggested that the word "alive" should be inserted in the form, so as to avoid the possibility of such things happening. Passing on to the uncertified deaths as inquired into by the coroner, Mr. Lowndes quoted the recommendation of the committee that the preliminary inquiries as to whether an inquest should or should not be held should no longer be left to the coroner's officer to decide, and as concerning coroners' inquests he quoted the following verdict of a coroner's jury which is worthy of the men of Gotham: "Child, three months old, found dead, but no evidence whether born alive." The recommendations of the Select Committee have not yet passed into law; but we can only echo Mr. Lowndes's wish that the Legislature will improve our system of death registration.

THE DIFFUSION OF SMALL-POX.

THE decrease in the cases of small-pox recorded in the week ended Aug. 10th—namely, a total of 54, as compared with over 100 in the week preceding—was not maintained last week, when the number rose to 81. Whilst, however, showing such a rise, the week was not one of steady increase, inasmuch as on one day alone the admissions to hospitals of the Metropolitan Asylums Board numbered 29, and on another 10; and earlier in the week one day accounted for 17 removals, three days in this way contributing 56 of the 79 admissions effected in the week. As may well be supposed, many sanitary areas sent cases, though, speaking generally, those invaded were in the eastern and southern parts of the metropolis. There was happily only one registered death in the week, this being of an individual aged over twenty years. The deceased belonged to the parish of St. Martin-in-the-Fields, and no statement was made as to vaccination. At the close of the fourth week of July there were just on 200 patients under treatment for small-pox in hospital, but last Saturday the number had swollen from 237 and 273 to 336; and the earlier days of the present week showed no falling off in the fresh patients being admitted. Round London there was some little small-pox in the West Ham vicinity, and one or two cases in other parts of the suburbs. In the provinces the chief centre of the disease seems to be in the Lancashire towns, where many cases were recorded last week. In the preceding week some eight attacks came to light at Oldham, and these were treated in the Moscow Hospital

Digitized by Google

at Highmoor, outside the borough, where last week, as well as in the adjoining urban district of Chadderton, there were multiple cases reported, the circumstances calling for the ever ready measures of prevention which are adopted in these towns. At Wigan, too, there has been a smart outbreak, and cases which have occurred recently at Horwich and at Bradley Fold, in the absence of proper hospital accommodation, have been taken into the hospitals of adjacent councils at a weekly cost per patient of £7 7s. A single case occurred last week in the Greengate division of Salford, and 6 cases were recorded in Manchester, the patients being promptly looked to and isolated, the disease having thus made but little headway in the city. In Dublin in the week ended Aug. 10th there were 5 fresh admissions to hospital, 2 discharges, and 28 acute cases still under treatment, in addition to 4 convalescent patients at Kilmainham Hospital.

SCHOOL BOARDS AND STONE-THROWING.

A QUESTION of liability on the part of the School Board was recently discussed in the West London Police-court. In this case the plaintiff objected to the nuisance caused by children in a school playground breaking the neighbouring windows by throwing stones, and required the Board to put up a wire fence for his protection. The presiding magistrate maintained that the children alone were responsible for their misdemeanour—a somewhat barren decision, it would seem, unless someone else were in turn responsible for them. We presume that though, happily, the boy need not in regard to this dangerous peccadillo be father to the man, he is man enough in the person of his father to make amends for his offence. The parent, in short, is liable, and the School Board, which does not include stone-throwing in its syllabus of instruction, will not replace him in his parental privilege. This does not mean that the officials of the Board should sit with folded hands and take no notice of what is going on within their own premises. Stone-throwing must be promptly checked, and its prohibition strengthened by an exemplary penalty. If this be done perhaps wire fences and the like palliatives may be surrendered in favour of the radical cure. If it is not done we fail to see under what moral or legal sanction the shadowy memory of a parent's home lessons on the golden rule can suffice to transfer the Board's responsibility.

MEDICAL PRACTICE IN BORNEO.

PATIENTS within the borders of our United Kingdom have been known to complain that they were sometimes compelled to endure hard treatment at the hands of their medical attendants; but if, as has been authoritatively asserted, to derive comfort from the superior woes of others be indeed characteristic of suffering humanity, we recommend all who may deem themselves medically aggrieved to take note of the manner in which (according to the *Sarawak Gazette*) the native medical men of Borneo are wont to serve the unhappy creatures whose hard fate it is to become the victims of their tender mercies. Private Unong (of Kabong) having caught some river fish called "buntal" proceeded to cook them for his dinner, but only partook of three small ones. In a very short time he began to experience most peculiar sensations, the like of which he had never felt before. His lips and tongue grew numb and seemed as though they were swelling to an enormous size, and before long a similar kind of feeling gradually extended down his trunk and limbs until it pervaded pretty nearly the whole of his body. He contrived, however, to summon help, and when his comrades perceived his condition they promptly called in several native hakims, who lost no time in subjecting the afflicted one to a course of treatment *secundum artem Malayensem*. There is a root indigenous to Northern Borneo which is popularly supposed to be endowed with some very marvellous properties, including, amongst the rest, the power of inhibiting intoxication from alcohol. With this remarkable drug as basis a mixture called in the vernacular "akar bangun" was fabricated and administered to the luckless patient as long as he could be induced to swallow it. The gentle physicians then fastened him upon a kind of shelf over the kitchen fireplace and inaugurated a species of slow roasting with what they, no doubt, thought was music of a high order. How long this stage of the "cure" continued is not clear, but evidently the Bornean hakims were methodical people with large ideas regarding their personal dignity and constitutionally opposed to anything resembling hurry. At length a violent fit of vomiting supervened, which afforded the semi-incinerated patient great relief; and, as this was apparently the crisis aimed at, he was lifted off his shelf, whereupon he incontinently fell into a deep sleep, which lasted two days and two nights. It must not be supposed, however, that the cure was now complete—far from it. During Unong's prolonged somnolence another compound (which is described as "a most efficacious medicine") had been prepared, the chief ingredient consisting of "shavings of porcupines' teeth," and this the poor fellow was compelled to drink as a preliminary to further roasting. Eventually the private, who must have had a wonderfully strong constitution, declared that he was "fit for duty," and thus escaped from the hakims' clutches. His case is surely a notable example of a sick man's recovery in spite of his physicians.

THE "SAFE ADMINISTRATION OF CHLOROFORM VAPOUR."

MR. ALFRED WRIGHT, late medical superintendent of the Westport Hospital, New Zealand, writes that after an experience of forty years he believes chloroform can be safely given if care be given to the following points. The administrator should devote his sole attention to the chloroform. The chloroform should be administered from an inhaler which admits of accurate regulation of the quantity of vapour given. This desideratum is best met, he thinks, by employing the most recent modification of Junker's inhaler, called the "regulating chloroform inhaler," fitted with the feather respiration indicator. Mr. Wright, although he has never had a death in his practice, believes all fatalities are due to respiratory failure, and he describes the well-known symptoms of death by overdose. In cases attributed to heart failure Mr. Wright believes an error of diagnosis is in the hurry of the moment made, and the true cause of death in all cases is a chemical change in the blood which prevents its due aeration. He emphasises the dangers of "happy-go-lucky" administration of chloroform.

THE EXPLOSION AT THE MILE-END INFIRMARY.

WE are all aware that it is easy to be wise respecting causes and effects after an event; yet we may even then be wise to great advantage, and we are therefore justified in accepting whatever practical truths may be learnt from the unpleasant teachings of disaster. The recent explosion at the Mile-end Infirmary is an example of this class which is widely instructive. What mischievous consequences might have resulted under conditions less favourable to the safety of the inmates we may judge from the damage actually done. The upheaval of the garden and front corridor, the destruction of floors in two wards and of many windows, and finally an outbreak of fire which wrought considerable havoc in the basement of the building—these effects may suffice to suggest what further evils might have been. We have to consider also the fact that the infirmary contained at the time of this occurrence over 350 inmates, many of them seriously ill, and some possibly infirm in mind as well as in body. It

Digitized by Google

was a happy circumstance that this accident occurred in the daytime. Had it happened at night the efforts of officials could not have been equally prompt and effectual, and the consequences of a possible panic would be difficult to estimate. Notwithstanding the fortunate absence of these graver features, however, it would be folly to omit the use of any and every precaution which may ensure safety in a imilar emergency in future. The importance of providing means of exit from all public buildings is now generally admitted, and it has not been overlooked in the construction of modern hospitals. In the older buildings it is possible that there may still be room for improvement in this particular. The like may be said in regard to hydrants and hose, which in the hands of a few capable men prevented the accident at Mile-end from becoming a catastrophe. As regards the cause of this occurrence, an official inquiry will doubtless enlighten and instruct public opinion. A point of evident importance, though clearly under-estimated in this case, is to be found in the fact that though the garden soil is said to have been impregnated with gas escaping in large volume from a main pipe, no means were used to prevent the use of lighted matches by persons walking in the grounds.

THE BATTLE OF THE CLUBS AT CORK.

IT was very gratifying to gather from our Cork news that there was a reasonable prospect of the questions in dispute between medical men and the clubs being discussed in an adequate manner and under conditions giving a fair prospect of success. The Mayor of Cork has most properly interested himself in the settlement of a dispute which is disastrous to all parties concerned. No use of his Worship's office could be more appropriate than this one of mediator between a liberal profession and bodies with which it wishes to deal liberally, while preserving due respect for its own grave and responsible interests. The profession as requested sent six representatives to meet an equal number of representatives of the clubs, the Mayor presiding. But we regret to learn from our Cork correspondent, as we go to press, that the proceedings terminated without any understanding being arrived at.

THE lectures of the Royal College of Physicians of London for the coming year will be delivered as follows: The Goulstonian Lectures by Dr. Patrick Manson, the Lumleian Lectures by Sir Dyce Duckworth, the Croonian Lectures by Dr. George Oliver in 1896, and by Dr. Greenfield in 1897. The Bradshaw Lecture will be delivered on Nov. 7th, 1895, by Dr. Bradbury.

THE RELATIVE HEIGHTS AND WEIGHTS OF BENGAL PRISONERS.

BY SURGEON-CAPTAIN W. J. BUCHANAN, M.B. DUB.,
SUPERINTENDENT, CENTRAL GAOL, BHAGALPUR, INDIA.

THE following table has been compiled from office records in the Central Gaol, Bhagalpur. It is based upon the recorded heights and weights of over 8000 male adult prisoners, most of whom have been admitted to Bhagalpur Gaol, all in good health, in the last five years. All those recorded as having been admitted in indifferent or bad health have been excluded from these figures. They, therefore, represent the average weight for each height of healthy men. The figures differ slightly from a similar table published by me in the *Indian Medical Gazette* some time ago; that list was found to be based in some instances on too few cases, men over 5 ft. 8 in. not having been found in sufficient numbers. This has been rectified by an examination of all the taller men at present in the gaol, and by use of figures kindly supplied by the medical superintendents of many other gaols in this province. The figures have been found to be applicable to most parts of the province of Bengal, excluding, of course, the hillmen, such as are found in Nepal and the Darjiling Himalayas. They have been tested to a large extent also in the central gaol, Nagpur, in the Central Provinces, and found to apply almost exactly. They do not, however, apply to the inhabitants of the North-West Provinces, Oudh, and the Punjab, where the men are of a taller and heavier type. They contrast markedly with figures recorded for heights and weights of European adults. As no table of the kind appears to have been published before, it is considered they will prove interesting to anthropologists in Europe as well as useful to medical officers in charge of gaols in India. For practical purposes I find the following rule sufficiently accurate for ascertaining the normal weight of a man of this class. Taking 100 lb. as the correct weight for a man of 5 ft., if we add 3 lb. for every inch above 5 ft. we shall arrive at a fair average normal weight—e.g., a man of 5 ft. 5 in. = 5 × 3 + 100 = 115 lb. It must be remembered that a prisoner passed as of "good health" is considered liable to hard labour. I maintain that if a man of this part of India reaches the standard above prescribed he will be capable of performing the severest form of hard labour.

Height.	Weight.	Height.	Weight.
5 ft. 0 in. ...	98 lb.	5 ft. 7 in. ...	118 lb.
5 ,, 1 ,, ...	100 ,,	5 ,, 8 ,, ...	122 ,,
5 ,, 2 ,, ...	103 ,,	5 ,, 9 ,, ...	128 ,,
5 ,, 3 ,, ...	106 ,,	5 ,, 10 ,, ...	132 ,,
5 ,, 4 ,, ...	108 ,,	5 ,, 11 ,, ...	154 ,,
5 ,, 5 ,, ...	112 ,,	6 ,, 0 ,, ...	138 ,,
5 ,, 6 ,, ...	115 ,,		

In his work, "La Donna Delinquente," Lombroso gives a rule for computing the normal weight of an individual derived from measurements of Italians. The rule is as follows: "A person is regarded as having a weight equal to the average in whom the number of kilogrammes which represent the weight is equal to the number of centimetres by which their statures surpass the metre." This is an exceedingly rapid rule for calculating weights for height if we use the decimal measurements. It works out as follows in pounds and inches: starting with 110 lb. for 5 ft., for every inch above this 5 lb. are to be added. This is too high an estimate for ordinary peasants of the province of Lower Bengal, but as far as my experience goes of men of the North-West Provinces and Punjab in India I think it would prove fairly exact.

Bhagalpur.

THE BATTLE OF THE CLUBS AT BRUSSELS.

(FROM OUR SPECIAL COMMISSIONER.)

THE struggle between the medical profession and medical benefit societies has reached a most acute stage in Belgium. The situation across the Channel is identical with what exists in Great Britain and Ireland. The only difference rests in the fact that the medical men who practise in the Belgian capital have created a much better fighting organisation than anything of the sort actually in existence among members of the profession on this side of the Channel. There are about 450 medical men in practice at Brussels, and of these 430 are paying members of the Collège des Médecins de l'Agglomération Bruxelloise (Syndicat). For the sake of brevity this association is generally called Le Syndicat Médical. Each member, to cover working expenses, pays an annual subscription of 3 fr. and pledges himself to pay any levy, whenever made, so long as the sums raised from time to time do not exceed in all the sum of £4 in one year. As yet no levy has been made, and the 430 annual subscriptions of 3 fr. each have sufficed to cover all the working expenses. On the other hand, ninety-five mutual aid or benefit societies of Brussels have federated and elected a general managing council. This is known as the Federation des Mutualists. The members of the Federation number about 12,000, who generally pay 2 fr., or 1*s.* 8*d.*, per annum for medical attendance for themselves and their families, and this represents in all a population of at least 50,000 persons. The

Digitized by Google

Federation of the Mutualists had engaged the services of eighteen general practitioners and of two specialists. The salaries paid varied from 700 fr. to 1400 fr. The salary was estimated according to the number of Mutualists residing in the district of each officer. The officers employed had to reserve two hours for consultations every day and to go to the homes of the patients who could not come to their surgeries. They had to see patients whatever the nature of their illness and to help in case of operations. An extra allowance of 25 fr., or £1, was made for accouchements or miscarriages, and 2 fr. for vaccinations at the surgery or 3 fr. for vaccinations at the patient's home. But as these extra allowances had to be paid to the medical man by the patients themselves it very often happened that the officers failed to obtain the money. It is absolutely impossible to estimate what this rate of payment represents per visit. The medical officers in central districts have a larger number of patients, but the distances are much shorter. A medical man who had a suburban district showed me his books, and, roughly speaking, I should say that he gave fifteen consultations per day, Sunday included. His salary was 1200 fr. per annum, so that he would receive on an average 22 centimes, or a trifle less than 2½*d*., per consultation. This, however, is no rule; the proportion of payment varies greatly per district. It must also be borne in mind that the cost of living is much cheaper in Belgium than in England; that where a high-class consulting physician would receive in London a two-guinea fee, in Brussels from 16*s*. to £1 would be given; and that in ordinary practice among the poorer classes fees of one and two francs are considered very acceptable.

As in all other countries, a number of comparatively well-to-do persons have crept into these "mutualist" or benefit societies; indeed, some middle-class societies have been constituted that should never be allowed to contract for such cheap medical service. These are the Fraternelle Belge, the Mutualité Commerciale, and the Société des Voyageurs de Commerce. It is objected that commercial men and commercial travellers can well afford to pay for medical attendance, and cases are cited of members of these societies who are in receipt of incomes equal to even £1000 a year, yet they expect to obtain medical attendance for themselves and their families in exchange for a payment of only 2 fr. (1*s*. 8*d*.) per annum. A case was described to me of one of these wealthy mutualists, as the members of such societies are called, who paid a subscription of 4 fr. or 5 fr. a year. He had an operation performed, and gave the operating surgeon, who was not in the service of the Mutualist Federation, a fee of £24; but he gave nothing to the medical officer of the Federation who also attended him, and he obtained from the Federation medicaments, bandages, &c., to the value of £6. If he could afford to give the operating surgeon £24, why should he not also pay at a proper rate for his medicaments and his ordinary medical attendant? Another medical man related to me how he had been called up in the middle of the night to attend the wealthy owner of a large establishment, who refused to give him a fee on the ground that he paid 1*s*. 8*d*. per annum to a mutualist society. Under these circumstances the Medical Syndicate opened communications with the Mutualist Federation. After lengthy negotiations the Federation suddenly offered to increase the salaries, in some cases to the extent of 500 fr. (£20) per annum. Formerly the increase allowed never exceeded £4 a year. The Medical Syndicate urged that they were not seeking to obtain more money for medical services. That was not the principle at issue. There was no lack of medical men who would gladly give their services for nothing if it was to relieve a genuine case of poverty, but they absolutely refused to attend rich men on the same terms as the poorly paid labouring classes. At last the Federation replied that they would endeavour to eliminate the well-to-do members of their societies; and, acting on this principle, they had refused to admit to their ranks the Israelite Benefit Society and the Société des Sauveteurs. The Federation, however, gave no sort of explanation as to how they proposed to eliminate the well-to-do element. They, on the contrary, refused to take any so-called inquisitorial measures so as to ascertain what was the income of their members. The Medical Syndicate now replied that, if the Mutualist Federation could not or would not do this work, the medical men themselves were quite prepared to carry it out; and claimed that the officers in the service of the Federation should have the right to refuse to attend such members of the mutualist societies as could afford to pay a proper fee. This, and this only, is the point at issue. All other questions raised are of secondary importance. The Federation, however, refused to negotiate further or to in any way amplify the vague promise they had made. Thereupon the twenty medical men in the service of the Mutualist Federation, obeying with exemplary discipline the orders issued by the Medical Syndicate on July 5th last, gave in their resignations on July 6th. Conforming, however, to instructions received from their syndicate, they have from motives of humanity continued to attend the patients actually under treatment when the movement commenced.

To meet this emergency the Federation offered high salaries to anyone who would undertake to replace the medical men who had resigned. The scratch staff of medical officers thus got together were quite incapable of doing all the work required. There were never at any time more than eleven enrolled, and I am assured that at the present moment only four of these render any really effective service. Being thus absolutely incapable of supplying the medical assistance which the Federation are pledged to provide for all their members, an announcement was made that any member of the affiliated mutualist societies might consult any medical man he chose and pay him a fee of 2 fr. The money would be reimbursed to the member by the society to which he belonged, only he was especially recommended not to consult any of the twenty officers who had resigned. The Medical Syndicate met this manœuvre in a very effective and simple manner. They issued orders that all practitioners, except the twenty officers in question, were to refuse to give receipts for the 2 fr. fees offered by the mutualists. The latter were, therefore, unable to prove that they had paid the 2 fr., and consequently could not be reimbursed. They then naturally, and in spite of the recommendation received to the contrary, began to gravitate back to the Federation officers, from whom they had no difficulty in obtaining the receipt for the 2 fr. Thus these officers are getting a number of their patients back again, and, financially speaking, on very much better terms.

In this struggle the Medical Syndicate have no power beyond that derived from the voluntarily accepted discipline of the members. Fortunately, this discipline has been very strictly maintained. The Federation had appointed a medical man, with the high salary of 4000 fr. per annum, as the chief of their medical service. For the success of the movement it was absolutely indispensable to dislodge this adversary. Measures were accordingly taken. He was systematically "cut" by the whole of the profession; no one would enter into consultation with him. If he came near his old medical friends they put their hats on their heads and their hands in their pockets and refused to shake hands with him or to speak to him. If he entered a café or any other public place all the medical men present at once rose and left. He was medical officer to one of the Brussels theatres; his colleague, the senior medical officer of the theatre, went to the manager and threatened to resign his post if his colleague was not at once dismissed. This request was immediately granted. The whole medical staff of the Civic Guard of Brussels tendered their resignations if the officer, who was one of their colleagues in that service, was not dismissed. Though the position of medical officer to the Civic Guard is only an honorary office it is much envied by the profession, as it generally brings with it a considerable increase of private practice. The colonel of the Civic Guard, who did not at all relish losing the services of all the medical men enrolled, at once acted as requested. The result was that the chief of the newly constituted medical staff serving the Mutualist Federation found life absolutely unendurable, and finally came to the Medical Syndicate, apologised for his conduct, joined the Syndicate, undertook to obey their orders, and therefore had to at once resign the appointment the Mutualist Federation had given him. As already mentioned, I am assured that the Mutualist Federation have now only four medical men at their service who are really capable of doing the work required.

Brussels, Aug. 20th.

THE HORSE SICKNESS OF SOUTH AFRICA.

THE recently issued report of the Colonial Bacteriological Institute, Graham's Town, Cape of Good Hope, for the year 1894, is mainly devoted to work done in the investigation of the South African epizootic known as "horse sickness." This

Digitized by Google

disease seems to be present in some parts of Cape Colony every year, and at considerable intervals assumes the proportions of a formidable epizootic. During the two years 1854–55, when the colony was much less extensive than at present, it carried off 64,800 horses, mares, and foals, and the mortality in the recent outbreak of 1891–92 has been computed at 13,900 horses and 140 mules. Systematic investigations of this disease by a trained observer were commenced in 1887, when Mr. Joshua Nunn, F.R.C.V.S., as a result of his observations in Natal, concluded that it is not anthrax, and that it is not contagious. In June, 1891, Dr. Alexander Edington of Edinburgh became director of the newly created Bacteriological Institute, and has continued the investigation of horse sickness since the beginning of 1892. The death-rate of animals attacked is from 95 to 99 per cent. Invariable post-mortem phenomena are copious effusion of serum into the pericardium, pleuræ, and pulmonary tissue, the presence of yellow solidified serum in the subcutaneous tissues of the neck, and of yellow fluid in the trachea. Death is immediately due to the effusion into the pericardium, lungs, and pleuræ. The effusion into the lungs is not only along the lines of the interlobular septa, but is actually into the air cells themselves, so that the animal may be practically drowned in its own blood serum. Dr. Edington found that not only is inoculation of healthy animals possible, but that if the material for inoculation be suitably selected a fatal result will constantly follow. In the blood of all horses dying from uncomplicated horse sickness, after a period of nine or ten days' illness, reckoned from the date of infection, he discovered peculiar oval bodies much larger than micrococci. They are composed of a delicate cell wall with flattened and thickened ends, containing a peripheral substance which stains much less deeply than the cell wall, while centrally there is a round or oval body that stains deeply. In size they may be 3·5 μ long by 2·5 μ broad, in other cases 5 μ long by 3 μ broad, while in a few exceptional instances they may be nearly spherical with flattened ends. The ends or poles are characteristic. They are always flat or slightly concave from without inwards, and the extreme points of each flattened pole are usually thickened, so that there is an appearance as of two micrococci lying upon the free ends. The body placed centrally is evidently a nucleus, and stains very deeply. The staining fluids are 1 per cent. aqueous solutions of dahlia, methyl violet, and fuchsine. Cover glasses are prepared with thin films of blood which are dried in the air, quickly fixed by passing thrice through the flame of a Bunsen burner, stained for three minutes, washed in sterilised water, dried, and mounted in balsam. Numerous and varied cultivation experiments were unsuccessful. The organism is not a bacterium, but the vegetative spores of a pathological mould, the mycelium of which Dr. Edington has also discovered. He has proposed for the organism, pending the further working out of its life history, the name of œdemamyces, and for the disease it produces œdemamycosis.

In Cape Colony humanised vaccine lymph is distrusted on account of the prevalence of leprosy, and shortly after Dr. Edington's arrival in the colony he advised the Government that the preparation and public supply of calf lymph should be one of the functions of the Bacteriological Institute. The suggestion was adopted and the work was soon carried out on a great scale, 146,344 tubes having been sent out during 1894, greatly to the financial advantage of the Institute. On April 30th, 1895, he made the very important announcement, in a letter addressed to the Secretary for Agriculture, that he had discovered a vaccine protective against horse sickness. At the same time he requested that he might be admitted to a share in the profits derivable from the sale of his vaccines; but the official reply was that "any discoveries you may have made or may make whilst engaged in investigating the diseases of stock, for which purpose you specially engaged yourself to Government, are, as a matter of course, the property of the State, and I am to inform you that your claim to a share of the profits on any vaccines resulting from your investigations at the Institute cannot be entertained." Dr. Edington afterwards unreservedly withdrew any claim which he might seem to have advanced to a proprietary right in any of the discoveries made in the Institute or in the preparation of the vaccines. The results attained under his management were commended last July by a select committee appointed by the House of Assembly to inquire into the working of the Bacteriological Institute.

FORTY-NINTH REPORT OF THE COMMISSIONERS IN LUNACY TO THE LORD CHANCELLOR.[1]

THE Annual Report of the Commissioners in Lunacy for the year 1894 commences with the statement that the total number of lunatics, idiots, and persons of unsound mind included in the returns, statutory and other, made to their department was, on Jan. 1st, 1895, 94,081, being an increase over the corresponding number on Jan. 1st., 1894, of 2014. The total is made up of 8250 private, 85,089 pauper, and 742 criminal patients, and the summary shows a decrease of 61 in the private class, but increases of 2064 and 11 respectively in the pauper and criminal classes The private patients appear to have increased by 28 in county and borough asylums and by 6 in provincial licensed houses, but they decreased on the other hand by 59 in registered hospitals, by 23 in metropolitan licensed houses, by 3 in naval and military hospitals, and by 10 as regards single patients. The pauper patients appear to have increased very generally, with the exception of a decrease of 1 in registered hospitals and 9 in ordinary workhouses. In only eight of the fifty-six "union" counties in England and Wales was there a decrease in the number of pauper lunatics. The increase was largest—viz., 482—in the county of London, but contrasts favourably with that of 1893—viz., 800. In Lancashire it amounted to 202, which was, however, less by 63 than the increase of 1893. In Yorkshire and Essex, where the increases were 186 and 141, these increases were respectively 75 and 81 more than in 1893. An unusual feature is the increase in the number of out-door lunatic paupers, this class having for many years shown a marked tendency to decrease.

The Commissioners again discuss the important question as to whether the increase in the total number of lunatics implies an increase of insanity in its more active forms. In connexion with this matter they compare the average annual increases since 1859 and point out that the average annual increase in the last six years (1889 to 1894 inclusive)—viz., 1623—is less than that of the decades 1859 to 1868 and 1869 to 1878, when it was 1641 and 1671 respectively, in spite of the large increase of the general population. The proportion, however, of the total yearly admissions of lunatics into institutions for lunatics and as single patients to total population has increased almost continuously from 1869 to 1893, but it is gratifying to find that there was a slight decrease in 1894, the ratio per 10,000 of admissions to population dropping from 5·99 to 5·88. This steady increase of admissions, with the exception of 1894, is attributed partly to the reception in recent years of more cases of mental decay resulting from old age, the ratio of old age admissions to total admissions being 2·2 per cent. higher in 1893 than in 1883.

An important factor in the accumulation of cases is the diminished death-rate in asylums in the last thirty-six years, the ratio falling from 10·31 per cent. of the average numbers resident in the decade 1859–68 to 9·78 for the past six years. Against this, however, must be set the fact that the recovery rate has increased, the ratio last year being 40·31 per cent. of the total admissions, or 1·86 higher than in 1893, and 0·65 higher than the average of the ten years including 1894. The diminished death-rate and increased recovery-rate, however, when balanced against each other are calculated to account for 4228 of the total number under care at the end of 1894. The figures shown in the report certainly give no cause for alarm as to the prospect of a marked increase in the number of cases of insanity in proportion to the population, and the increasing recovery-rate and diminishing death-rate are matters upon which those responsible for the management of institutions for the insane throughout the country are to be heartily congratulated. The report contains the usual statistical tables which space will not permit us to enter upon here. Under the head of County and Borough Asylums the Commissioners refer to the desirability of the establishment by local authorities of special accommodation for pauper idiot and imbecile children, of which there is great lack at present, the association of these children with the adult insane being an undoubted evil. A separate block for this class has been

[1] London: Eyre and Spottiswoode. 1895.

Digitized by Google

built at the Northampton County Asylum. The Commissioners express their strong impression of the need of cheap accommodation for the insane who are not paupers, but who cannot afford to pay much for their treatment, and they also desire to advocate the extension of lunatic hospitals on a charitable basis

The Annual Report of the Commissioners always contains some unpleasant reading, and as evidence that patients are not the only people liable to injury in asylums, may be mentioned the fact that no less than three medical superintendents were the victims of murderous assaults by patients during 1894—viz., Dr. Wigglesworth at Rainhill, Dr. Deas at Exeter, and Mr. Case at Leavesden. The Commissioners urge these facts as an additional argument for the recognition by county councils of the arduous and dangerous duties of those having the care of the insane, and the desirability of the universal establishment of pensions for long service or accident. The number of suicides in county and borough asylums was ten only, but there is a rather long list of fatal casualties during the year, and a remarkable death is reported—namely, that of a man from shock following gastrostomy, at which operation nearly 1¼ lb. of nails, buttons, wire, &c., were removed from the stomach.[2]

A large part of the remarks about registered hospitals consists of the Commissioners' report on their special inquiry respecting the death of a patient while in the "dry pack" at the Holloway Sanatorium, and they comment on the fact that their power of control over hospitals for the insane is very limited, and think it ought to be extended by the Legislature. The new regulation on the subject of mechanical restraint, which is found in Appendix P in the Report, is apparently to some extent the outcome of this unfortunate case. The Commissioners report satisfactorily, upon the whole, of the condition of licensed houses throughout the country, though they suggest alterations and improvements in several institutions. The Report closes with the Commissioners' expression of regret at the death of their colleague, Mr. James Wilkes, who, previously for fourteen years medical superintendent of the Stafford County Asylum, had been a Commissioner since 1855.

THE BRITISH INSTITUTE OF PUBLIC HEALTH.

THE fourth annual congress of the British Institute of Public Health assembled at Hull on Aug. 8th, and was largely attended not only by members of the Institute but by official delegates from upwards of seventy municipal authorities, County Councils, School Boards, Metropolitan Vestries and Boards of Works, &c.

The opening ceremony was the formal reception of the visitors on the afternoon of Aug. 8th at Hymers College by Alderman Richardson, who is Mayor of Hull and President of the Congress. He said that this visit of the Institute was very gratifying to the people of Hull, especially as this was the first time that such a meeting had been held in a provincial town. Hitherto the Institute had met in the metropolitan cities of London, Edinburgh, and Dublin, and the selection of Hull on the present occasion was very acceptable to the inhabitants. Their population in the year 1847 was only about 70,000, and the death-rate was 31 per 1000; in 1894, however, the population had risen to over 216,000 and the death-rate had fallen to 16·9 per 1000. A very large sum had been expended in producing this happy result, but the money had been well laid out, because an improvement in the health of the people resulted in an increased capacity for work and for enjoyment of life. Hull was an ancient as well as a prosperous town; its charter of incorporation dated back to 1428, and was the second of the municipal charters of the kingdom.

The Sheriff of Hull and the Mayors of Huddersfield, Folkestone, and Birkenhead having spoken, Professor W. R. Smith, President of the Institute, replied that his first duty was to thank the mayor and corporation for inviting the Institute to hold its congress this year in Hull. They were also greatly indebted to his worship for inducing the various municipalities and county councils to send nearly 300 delegates to assist in their deliberations. The council of the Institute were glad to have an opportunity of coming to Hull, it being the third port in the United Kingdom and the gateway to the great industrial centres of Yorkshire and the north of England. It was worthy of note that the Hull death-rate for 1894 was only 16·9 per 1000, and that this succeeded a death-rate of 20·2 per 1000 during the previous decade. The death-rate from zymotic diseases was rather high during 1893, being as much as 4 per 1000, and it was only right that they who came from districts which were not seaports should recognise that for their low mortality from such diseases they were under deep obligations to Hull and other towns similarly circumstanced. The high death-rate in 1893 was, in fact, mainly caused by deaths from cholera, and it was very satisfactory to those who lived in inland places that that great scourge was promptly dealt with at the ports and prevented from spreading in the country.

Sir Henry Littlejohn said that the corporation of Edinburgh had expended nearly three-quarters of a million in improving the sanitary state of the city.

Sir Charles Cameron expressed his opinion that no better arrangements for preventing the spread of cholera could be made than those which had been carried out at Hull. He thought that the expense of making these preparations should not fall upon Hull and the other seaports, but should be defrayed by the country at large.

The work of the four different Sections began on Friday, Aug. 9th, and concluded on the following Tuesday, and among the many interesting subjects introduced to the notice of the meeting may be mentioned Epidemic Cholera (Surgeon-Lieutenant-Colonel Pringle), Public Water-supplies for Rural Districts (Sir James Russell), Municipal Abattoirs and Meat Inspection (Dr. S. Marsden), Cremation (Sir Henry Littlejohn), and Dust and Refuse Disposal (Mr. S. J. Beaman). We print in our issue to-day the address of Dr. J. Spottiswoode Cameron, the medical officer of health for Leeds borough and President of the Section of Preventive Medicine.

At the conclusion of the work of the Sections votes of thanks were accorded to the chairman and governors of Hymers College for placing the building at the disposal of the Congress, to various local gentlemen who had entertained the members, and to the office-bearers of the Institute.

SHENTON *v.* SMITH:

THE CASE OF MR. HENRY LIONEL SMITH, M.R.C.P. IREL.

OUR readers are familiar with this case, but it is of such striking interest, not only to medical men, but to all whose duties bring them into contact with things official in our colonies, that we consider it right to report from time to time any progress that has taken place in the attempt to secure for Mr. Henry Lionel Smith something a little more tangible than sympathy in his admitted wrongs. The story will always bear recapitulation, for the details are a little involved, though the wrongs inflicted are very patent to comprehension.

In 1887 Mr. Smith received the post of acting medical officer at Albany. In the following year events happened during the transfer of the Albany Colonial Hospital to new buildings which resulted in the death of a patient suffering from enteric fever, the immediate cause of death being, as was alleged, exposure to cold. For this death a coroner's jury of three persons attached blame to Mr. Smith, and the Government dismissed him, an order being passed on July 9th, 1888, informing him that his tenure would cease at the end of the year. Mr. Smith proved that he was not responsible for the mishap, and that the act of the workmen which led to the exposure of the patient to cold was done in his absence and without his authority, and the Government allowed an appeal to the Secretary of State, who upheld the Governor's decision. Thereupon Mr. Smith—having been refused a hearing before the Medical Department in West Australia, while Sir William Robinson had declined to arbitrate after the first trial—entered a Petition of Right, with the Colonial Secretary as defendant. In this trial the jury disagreed, eleven being for Mr. Smith and one against, but in a subsequent trial they found for the plaintiff, with

[2] An account of this case by Dr. J. F. Gemmel, with an engraving of the nails &c. contained in the stomach was published in THE LANCET, vol. ii. 1894, p. 432.

Digitized by Google

£200 damages for wrongful dismissal. On the further consideration of whether the plaintiff had or had not been wrongfully dismissed the Court were divided, so that the original verdict remained undisturbed. In an appeal from this, specially allowed to the West Australian Government, before the Judicial Committee of the Privy Council on Feb. 2nd, 1895, the Court ordered that judgment be entered for the appellant (the Government of West Australia), but without costs in regard to the litigation in Australia.

Colonial civil servants, therefore, holding acting appointments can be dismissed at any moment by the Government without any reason being assigned, while the regulations are of no value as protection to them.

On July 12th, 1895, the following official letter was sent by the Royal College of Physicians of Ireland to Mr. Chamberlain, the new Secretary of State for the Colonies:—

"Royal College of Physicians of Ireland, Dublin,
"July 12th, 1895.

"SIR,—I am directed by the President and Fellows of the Royal College of Physicians of Ireland to bring under your notice the case of Mr. H. Lionel Smith, a Licentiate and Member of this College. In 1887 Mr. H. L. Smith was appointed acting medical officer at Albany, West Australia. After a year's service he was notified of his dismissal by the governors, owing to the death of a patient in the Albany Colonial Hospital, for which a coroner's jury, consisting of three persons, attached blame to Mr. Smith. An appeal to the Home authorities having been made in vain, Mr. Smith, by entering a Petition of Right, took proceedings against the Colonial Government. The jury gave a verdict in his favour, finding that the Government had no reasonable cause to dismiss him, and awarding him £200 damages and costs. Against this decision the Colonial Government appealed to the Full Court, and there the verdict of the jury remained undisturbed. A final appeal was then made by the Government to the Privy Council, and this tribunal has given its decision against Mr. Smith, thus affirming the right of Government to dismiss civil servants holding acting appointments without notice and without assigning any cause. The President and Fellows wish to disclaim any intention of disputing the decision of the Judicial Court of the Privy Council, but they think it their duty to lay Mr. Smith's case plainly before your notice. Mr. Smith was dismissed owing to a verdict of a coroner's jury, consisting of three persons, after a superficial inquiry, while subsequently, when the case was heard before twelve jurymen and the whole of the evidence taken, and the doctor's defence fully put forward, he obtained a verdict with £200 damages and costs. This must be taken as overriding the verdict of the jury at the inquest, and therefore Mr. Smith must be considered as free from all blame and to have completely vindicated his character. The result of this proceeding, however, is to Mr. Smith a very serious matter. He obtains no redress—not even the damages awarded him by the jury—and will have to pay his own costs of the colonial proceedings, and now, at the end of eight years of anxiety and litigation, he, although acknowledged to be innocent of the charge for which he was dismissed, finds himself, owing to a decision on a purely legal point, a ruined man, and obliged to begin the world again at an advanced age. For these reasons the College would most respectfully request you to take the matter into your careful consideration, so that Mr. Smith may in some way be compensated for all the hardships to which he has been exposed owing to what the President and Fellows cannot but consider as a wrongful dismissal.

"I am, Sir, your obedient servant,
(Signed) "G. P. L. NUGENT, M.D., Fellow and Registrar."

To this communication the subjoined reply was received, and we may note in passing that the courtesy of Mr. Chamberlain's words is enhanced in our eyes by the promptitude of his answer at a time when it is reasonable to suppose that even his talents for organisation have been strained.

"Downing-street, Aug. 8th, 1895.

"SIR,—I am instructed by the Secretary of State for the Colonies to acknowledge the receipt of your letter of the 12th ult., submitting a representation on behalf of Dr. Henry Lionel Smith, a Licentiate of the Royal College of Physicians in Ireland, in connexion with the circumstances in which he was removed in March, 1889, from the temporary charge of the Albany Hospital, Western Australia. I am to state that Mr. Chamberlain, while glad to think that Dr. Smith was able to disprove the professional misconduct in the case of the boy Webb, which was imputed to him in the verdict of the coroner's jury and in the Governor's minute, feels obliged to point out that the doctor's own evidence at the inquest contributed to the view taken by the jury and the Governor. He thinks also that it is to be regretted that Dr. Smith was advised to take legal proceedings in respect of matters which did not afford him a ground of action, and he feels that it is not possible for him to admit that the ultimate reversal of a verdict which should never have been given is ground for awarding Dr. Smith compensation at the expense of the public. I am to add that it would not in any case have been in Mr. Chamberlain's power to grant compensation in a case of this description, as Parliament has not placed at his disposal any funds from which it could be paid.—I am, Sir, your obedient servant,
(Signed) "JOHN BRAMSTON."

We quite understand that direct pecuniary compensation in such cases is always difficult to obtain. A strong Government (in using the word Government we are not alluding to a party, but to the British Constitution) does not make convenient arrangements beforehand, so that the results of mistakes may be obviated, for it does not anticipate making mistakes at all. But there are other methods than by the gift of so much money of showing practical sympathy with the plight of a citizen who has been caught in the cogs of the machinery of the Constitution and been disabled thereby; and we know that any favour shown to Mr. Smith, who has borne his grievous wrongs with the utmost pluck, will be hailed with acclamation by all who know his story. Reinstalment in the service from which he was dismissed would, we can believe, be awkward both to the department and its restored official, but the means at the disposal of Government by which Mr. Smith's case can be generously met are many.

With regard to the words "temporary charge" in Mr. Chamberlain's letter, it has been proved that Mr. Smith was led to believe that when he accepted office he was to hold for life (of course, subject to good behaviour), and he invested his money in his predecessor's practice on that understanding. We have no doubt that Mr. Smith regrets as much as anyone that he has been involved in legal proceedings which have ruined him, and have left him a middle-aged man with children to begin the battle of life over again, penniless and lying under the stigma (for it is no less) of being "a man with a grievance"; but what—what in the name of prudence even—was he to do? He took legal proceedings under the Petition of Right because, having been refused a hearing before the heads of the Medical Department in West Australia and arbitration by the Governor, he was recommended to take this course by his counsel, Mr. Hensman. Mr. Hensman is now a judge in the colony, and with Mr. Chief Justice Onslow (who ruled in Mr. Smith's favour) constitutes the highest legal authority in the colony. If Mr. Smith had declined to take Mr. Hensman's advice and had quietly sat down under a charge of constructive murder founded on the ill-considered verdict—"which should never have been given"—of an ignorant coroner's jury of three persons, would that have been prudent?

Eight years of his life, it is true, have been wasted in fruitless legislation, but at any rate the Secretary of State for the Colonies has admitted in his letter to the ancient corporation of which Mr. Smith is a Member that the charges of misconduct have been disproved, and that the coroner's verdict should not have been given. This is, we can well understand, highly satisfactory to Mr. Smith, but it will not give him back the time that he has wasted in kicking against official pricks, and it will not feed his children.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN thirty-three of the largest English towns 6518 births and 3884 deaths were registered during the week ending Aug. 17th. The annual rate of mortality in these towns, which had been 20·7 and 20·8 per 1000 in the two preceding weeks, declined again last week to 19·1. In London the rate was equal to 17·3 per 1000, while it averaged 20·4 in the thirty-two large provincial towns. The lowest rates in these towns were 9·1 in Croydon, 10·7 in Birkenhead, 13·3 in Bristol, 13·6 in Huddersfield, and 13·9 in Halifax; the highest rates were 25·5 in Manchester, 26·0 in Salford, 27·7 in Liverpool, 29·2 in Wolverhampton, and 31·0 in Preston. The 3884 deaths included 929 which were referred to the principal zymotic diseases, against 1178 and 1077 in the two preceding weeks; of these, 610 resulted from diarrhœa, 115 from measles, 82 from diphtheria, 48 from whooping-cough, 38 from scarlet fever, 33 from "fever" (principally enteric), and 3 from small-pox. These diseases caused the lowest death-rate in Plymouth, Swansea, Birkenhead, Halifax, and Newcastle-upon-Tyne; and the highest rates in Sheffield, Salford, Hull, Bolton, and Preston. The greatest mortality from measles occurred in Manchester, Salford, Swansea, West Ham, and Blackburn; from whooping-cough in Liverpool and Salford; and from diarrhœa in Norwich, Wolverhampton, Sheffield, Hull, Bolton, and Preston. The mortality from scarlet fever and from "fever" showed no marked excess in any of the large towns. The 82 deaths from diphtheria included 50 in London, 5 in West Ham, and 3 in Birmingham. Two fatal cases of small-pox were registered in Oldham and 1 in London, but not one in any other of the thirty-three towns. There were 336 cases of small-pox under treatment in the Metropolitan Asylum Hospitals and in the Highgate Small-pox Hospital on Saturday last, Aug. 17th, against 199, 257, and 273 at the end of the three preceding weeks; 79 new cases were admitted during the week, against 115, 60, and

Digitized by Google

54 in the three preceding weeks. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 2522, against 2347, 2423, and 2511 on the three preceding Saturdays; 357 new cases were admitted during the week, against 249, 247, and 281 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 171 and 159 in the two preceding weeks, further declined to 137 last week, and were 40 below the corrected average. The causes of 57, or 1·5 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Bristol, Nottingham, Leeds, Newcastle-upon-Tyne, and in eight other smaller towns; the largest proportions of uncertified deaths were registered in Birmingham, Liverpool, Salford, and Sheffield.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had declined in the three preceding weeks from 18·3 to 17·6 per 1000, further fell to 16·6 during the week ending Aug. 17th, and was 2·5 per 1000 below the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 13·6 in Aberdeen, and 15·4 in Glasgow and in Perth, to 20·8 in Dundee and 21·8 in Paisley. The 479 deaths in these towns included 60 which were referred to diarrhœa, 15 to whooping-cough, 7 to scarlet fever, 7 to measles, 6 to "fever," 4 to diphtheria, and not one to small-pox. In all, 99 deaths resulted from these principal zymotic diseases, against 84 and 102 in the two preceding weeks. These 99 deaths were equal to an annual rate of 3·4 per 1000, which was 1·2 below the mean rate last week from the same diseases in the thirty-three large English towns The fatal cases of diarrhœa, which had been 55 and 68 in the two preceding weeks, declined again to 60 last week, of which 31 occurred in Glasgow, 10 in Dundee, 7 in Edinburgh, and 5 in Aberdeen. The 17 deaths referred to whooping-cough were within 2 of the number in the preceding week, and included 9 in Glasgow. The fatal cases of scarlet-fever, which had been 3 and 4 in the two preceding weeks, further rose to 7 last week, of which 5 occurred in Glasgow. The 7 fatal cases of measles showed a slight decline from the numbers recorded in recent weeks, and included 4 in Glasgow and 2 in Paisley. The deaths referred to different forms of "fever," which had been 5 and 4 in the two preceding weeks, rose again to 6 last week, of which 4 occurred in Glasgow, where 2 of the 4 fatal cases of diphtheria were also recorded. The deaths referred to diseases of the respiratory organs in these towns, which had been 77 and 67 in the two preceding weeks, further declined to 57 last week, but slightly exceeded the number in the corresponding week of last year. The causes of 30, or more than 6 per cent., of the deaths in the eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 25·7 and 22·2 per 1000 in the two preceding weeks, rose again to 24·0 during the week ending Aug. 17th. During the past seven weeks of the current quarter the death-rate in the city has averaged 23·7 per 1000, the rate during the same period being 20·5 in London and 16·1 in Edinburgh. The 161 deaths registered in Dublin during the week under notice showed an increase of 12 upon the number in the preceding week, and included 21 which were referred to the principal zymotic diseases, against 25 and 27 in the two preceding weeks; of these, 16 resulted from diarrhœa, 2 from scarlet fever, 1 from small-pox, 1 from whooping-cough, 1 from "fever," and not one either from measles or diphtheria. These 21 deaths were equal to an annual rate of 3·1 per 1000, the zymotic death-rate during the same period being 3·8 in London and 1·7 in Edinburgh. The fatal cases of diarrhœa, which had been 24, 17, and 23 in the three preceding weeks, declined again to 16 last week. The mortality from whooping-cough corresponded with that recorded in the preceding week, while the mortality from "fever" showed a decline. The 161 deaths in Dublin last week included 36 of infants under one year of age, and 39 of persons aged upwards of sixty years; the deaths of infants were fewer than those recorded in any recent week, while those of elderly persons showed a marked increase upon recent weekly numbers. Four inquest cases and 1 death from violence were registered; and 54, or rather more than a third, of the deaths occurred in public institutions. The causes of 11, or nearly 7 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

MOVEMENTS OF THE MEDICAL STAFF.

SURGEON-CAPTAIN HICKSON relieved Surgeon-Captain M. P. Holt at Natal on June 27th. He is not in England, as stated in our issue of June 27th.

ARMY MEDICAL STAFF.

Surgeon-Major George M. H. Colman, M.D., retires from the service, receiving a gratuity. The undermentioned Surgeon-Captains to be Surgeon-Majors:—David Bruce, M.B., Edward H. Lynden-Bell, M.B., John Riordan, M.B., Robert H. Firth, F.R.C.S. Eng., Robert H. Moore, M.D., Alan E. Tate, Charles E. Faunce, and Henry J. Wyatt, F.R.C.S.I.

INDIA AND THE INDIAN MEDICAL SERVICES.

The Queen has approved of the following promotions among the officers of the Indian Medical Services made by the Government of India:—*Bengal Medical Establishment:* Surgeon-Lieutenant-Colonels to be Brigade-Surgeon-Lieutenant-Colonels (dated March 29th, 1895): Christopher William Calthrop, M.D., and William Alexander Crawford Roe. Her Majesty has approved of the retirement from the Services of the undermentioned officers:—*Bengal Medical Establishment:* Surgeon-Lieutenant-Colonel James O'Malley McDonnell, M.D. (dated July 29th, 1895). *Madras Medical Establishment:* Surgeon-Lieutenant-Colonel Henry Hyde (dated May 25th, 1895). Surgeon-Major A. E. J. Croly is appointed to act as medical officer on the Staff of the Government of India during the absence of Surgeon-Major H. Martin, M.B. Surgeon-Major W. A. Parker, A.M.S., in charge of the Sanatorium and Station Hospital at Mount Abu, is appointed to the Civil Medical Charge of the Station in addition to his own duties. Surgeon-Colonel D. O'C. Raye, Inspector-General of Civil Hospitals, Punjab, is granted three months' privilege leave. Surgeon-Captain T. W. Shaw, M.B., I.M.S. (Bombay), medical officer of the 1st Regiment, Central India Horse, and of the Western Malwa Political Agency, is granted leave to proceed out of India on private affairs for one year.

NAVAL MEDICAL SERVICE.

Staff-Surgeon P. W. Bassett-Smith to the *Magdala*. Surgeons: H. B. Beatty to the *Bellona* and D'Arcy Harvey to the *Impregnable;* A. F. Harper to the Royal Marines, Plymouth; H. F. D. Stephens, to the *Vivid;* and E. A. Spiller to the Royal Marines, Portsmouth.

YEOMANRY CAVALRY.

Middlesex (Duke of Cambridge's Hussars): Surgeon-Lieutenant Leopold Hudson to be Surgeon-Captain. Shropshire: Surgeon-Captain J. D. Lloyd to be Surgeon-Major.

VOLUNTEER CORPS.

Royal Engineers: 1st Devonshire and Somersetshire: Surgeon-Lieutenant J. Fuller to be Surgeon-Captain.

FIELD-MARSHAL LORD WOLSELEY.

The announcement of Lord Lansdowne in the House of Lords as to the successor to the Duke of Cambridge as military head of the army had been generally anticipated, and has been received, we think, with public satisfaction and confidence. Viscount Wolseley unquestionably had the best claim to the appointment, and it is generally recognised that the Government has made the best selection for the post. Lord Lansdowne was careful to explain that the Government would take time to consider the changes in the organisation of the War Office and the conditions under which the General Officer Commanding-in-Chief—if that is to be Lord Wolseley's new title—was to hold his appointment, and that Lord Wolseley accepted the office subject to those conditions. H.R.H. the Duke of Cambridge retains the Commander-in-Chiefship until Nov. 1st, and will consequently carry out the usual autumn inspections. It is quite possible that we are on the eve of great changes, that the scheme of Lord Hartington's Commission will be much modified, and that many administrative changes and reforms may be introduced in the near future.

THE CASE OF SURGEON-MAJOR CLARENCE SMITH.

This case will be in the recollection of our readers. The officer in question was called upon to resign the service, and from the statement of his case as far as published it seemed to us to be one eminently calling for further inquiry and consideration. We are glad to learn, therefore, that Surgeon-Major Clarence Smith has received a letter from the Madras Government inviting him, on behalf of the Secretary of State, to attend a commission composed of one officer with judicial experience and a military officer, the commission to be neither public nor judicial; Mr. Clegg's letter to be read and Surgeon-Major Smith to be examined on that letter, on his memorial, and on other private letters. It was further stated that Surgeon-Major Smith would be allowed counsel and the right to call witnesses, and the commissioners would exercise a similar right.

THE WAR IN MADAGASCAR.

The soldiers composing the French expedition have had a hard time of it in road-making and clearing the country and in overcoming deficiencies and difficulties of transport and commissariat, notwithstanding that there has been very little fighting. There is a good deal of ineffectiveness from sickness and other causes, amounting, it is even said, to 30 per cent. It is possible, however, that this percentage represents the rate of sickness of certain portions of the force rather than the general sick-rate of the whole force.

THE ARMY MEDICAL SCHOOL, NETLEY.

The *Army and Navy Gazette* of the 17th inst. states that at the recent examination at the Netley Army Medical School four probationers—two for the Army Medical Staff and two for the Indian Medical Service—failed to qualify in one or more of the subjects of instruction, and calls attention to the grave pecuniary loss thereby entailed on the State. If, as stated by our service contemporary, only one-third of the total marks in each subject be necessary to qualify, it seems surprising that four probationers should have failed to pass the examination.

EXPERIMENTS WITH THE LEE-METFORD BULLETS.

Experiments are to be carried out at an ammunition factory in Bengal with five kinds of Lee-Metford bullets in order to test the accuracy of their flight and their ranging power, the ulterior object being to secure a projectile that shall have some "stopping power."

"Audi alteram partem."

"OVER-OPERATING IN GYNÆCOLOGY."

To the Editors of THE LANCET.

SIRS,—Dr. William Duncan, in THE LANCET of Aug. 10th, says that "a man who has operated on a pyosalpinx or a suppurating ovarian tumour can in a quarter of an hour make it perfectly safe for him to attend a lying-in woman." This seems to me a very quick change, and I would not myself, if I could possibly avoid it, be a party to an arrangement whereby a man should go so quickly from operating on a septic condition in the abdomen to a midwifery case, or—and this is equally, if not more, important—from a case of puerperal fever to an abdominal section. The newly delivered uterus and the peritoneum when exposed by surgical means or by accident are both very prone to contract septic disease, and septic infection is not always easily got rid of even by the use of the most powerful antiseptics. Unfortunately it is not possible for any man in extensive practice, whether obstetric or surgical, altogether and at all times to avoid contact with septic mischief, and the serious question raised by Sir William Priestley is whether it is desirable that the obstetric physician should undertake a kind of work which is not obstetrics and which would multiply his chances of becoming a source of danger to a woman in labour. In reply, Dr. Duncan suggests that the obstetric physician would use antiseptics more diligently if he added abdominal surgery to his obstetric work. This might or might not happen, but if the assumption be granted it does not seem to me to follow that abdominal surgery should become a part of obstetrics. The physician might find in brain surgery an equally strong incentive to cultivate that cleanliness which, if I understand Dr. Duncan aright, is not sufficiently considered by those who practise obstetrics alone.

Dr. Duncan says he agrees with Dr. Herbert Spencer "that it would be a wise and gracious act on the part of the surgeons in every hospital to hand over to the obstetric physicians all the cases of disease of the female generative organs requiring abdominal section." In regard to abdominal surgery, however, if there is anything well ascertained it is the uncertainty of diagnosis, and the immense importance to the patient of the surgeon being ready when he opens the abdomen to deal with any condition he may find, and, perhaps, with a condition very different from that which he expects to find; hence the obstetric physicians could not properly, if they would, stop at the surgery of the female generative organs, and the obvious inference is that they should either confine themselves to obstetrics proper and to the preservation and repair of the generative tracts without opening the abdomen, or that they should undertake to become proficient in the whole range of abdominal surgery. There is a possible distinction between work to be done only through the anterior abdominal wall and that which may be done through the vagina; but there is no possibility of separating in any practical way the abdominal surgery of the female generative organs from the surgery of the abdomen generally.

Dr. Duncan has referred, and evidently with disapproval, to the division of duties at the Samaritan Free Hospital, where the work done through the anterior abdominal wall is in the hands of the surgeons, and the medical and vaginal work is in the hands of the physicians. In my humble opinion some such division is essential in a special hospital for diseases of women. There are rarely any midwifery cases in the Samaritan Free Hospital, but it has been judged wise to keep up the distinction as between those who do midwifery and those who do not. I have already indicated that this distinction is important on account of the liability of the newly delivered uterus and of the exposed peritoneum to septic infection. The distinction is essential in another way as a salutary check on the operating zeal of the surgeons. When Dr. Duncan calls in question Sir William Priestley's view that there is over-operating in gynæcology he overlooks the indisputable examples given, taking absolutely no notice of the more important of them. I do not think that anyone who considers the matter carefully, and knows the facts, will deny the pertinency of Sir William Priestley's remarks, for instance, on the recent "epidemic for the removal of the uterine appendages."

In the Samaritan Free Hospital unnecessary operations of this kind are prevented to a great extent, if not altogether, by the physicians. To me personally (and I presume the experience of my surgical colleagues is similar) it has occasionally happened that I have thought a patient could only be cured by the removal of her appendages, whilst a colleague who does not practise abdominal surgery has, in consultation, held a different opinion; consequently the operation has for a time been abandoned. In some of these cases further observation has proved that an operation was unnecessary, whilst in others it has justified the surgeon's view. But a little delay is better than too great haste in matters of this kind, for whenever there is room for doubt it is rarely an urgent question of life and death.

I consider Sir William Priestley's opinion incontrovertible that in the interests of the patient, and therefore of the institution, all special hospitals for women should "have some physicians who do not operate." Without this provision the patients have not the advantage which all patients should have—namely, that of a consultation in cases of doubt with someone not personally interested in operating. At the present moment this advantage is not available in many—I might say in the majority—of special hospitals for women, and, moreover, it is not available in those general hospitals in which the obstetrician does abdominal surgery. However eminent the men concerned may be, this arrangement is bad in principle and is not in accordance with the best traditions of the profession. It seems to me that in Sir William Priestley's suggestion, already carried out in at least one institution, is to be found the best solution of the difficulty that has arisen—namely, that it is a wise plan to attach a gynæcological surgeon to the obstetric department in every general hospital. In some cases the obstetric physician has so devoted himself to abdominal surgery that it might be well to give him the appointment of special surgeon,

Digitized by Google

and to elect as obstetrician someone who wishes to practise midwifery alone.

The division of duties at the Samaritan Free Hospital enables that hospital to concentrate its advantages as a school of abdominal surgery in a few hands. The importance of this to every special hospital was prominently brought forward by Mr. Hutchinson in the Address on Surgery to the British Medical Association. He distinguished specialists from special hospitals, remarking that "it is quite possible that the latter may, when the staff is large in proportion to the number of beds, cease to offer the advantages as regards individual experience which they are designed to do." A special hospital which does not offer to its staff superior opportunities for practice, and to its patients superior treatment, is worse than useless.

I am, Sirs, your obedient servant,

Portman-street, W., Aug. 20th, 1895. JOHN D. MALCOLM.

THE PICRIC ACID TEST FOR SUGAR IN THE URINE.

To the Editors of THE LANCET.

SIRS,—In a review with which my book on "The Urine" was recently honoured in one of the quarterly medical journals, I am found fault with for not mentioning that boiling is required to bring out the red colouration on the addition of a solution of picric acid and liquor potassæ in urine containing sugar. Now, the fact is that if a solution of picric acid (about a third) be added, with an equal quantity of liquor potassæ, to urine containing sugar a reddish colouration is produced in the cold. This is undoubtedly intensified on boiling, the fluid assuming a claret colour, which passes on repose and cooling to a deep port-wine colour. What, however, is of more significance, the same results ensue in perfectly normal urine. The reaction is more marked, however, in urine containing an abundance of uric acid. This test, then, is eminently fallacious, and should be discarded for either qualitative or quantitative analysis of sugar in the urine.

I am, Sirs, yours faithfully,

D. CAMPBELL BLACK, M.D.,
Professor of Physiology in Anderson's College Medical School, Glasgow.

Aug. 19th, 1895.

AN IMPOSTOR.

To the Editors of THE LANCET.

SIRS,—It has just come to my knowledge that an unknown person giving an address in Goswell-road, E.C., and writing under the name of Dr. G. R. Saunders, has put himself in communication with old St. Bartholomew's men, stating that he has just returned from New Zealand in distress and asking for pecuniary assistance. I am happy to state that my brother, Dr. G. R. Saunders, is now in New Zealand, and that such an intimation is entirely untrue. I shall be glad to hear from any of the victims of this person.

I am, Sirs, your obedient servant,

FREDERICK W. SAUNDERS, M.B. Cantab.

Chieveley House, near Newbury, Berks, Aug. 20th, 1895.

"SPECIALISM IN MEDICINE."

To the Editors of THE LANCET.

SIRS,—Your correspondent, "A General Practitioner," is, I think, in error when he describes overcharging as if it were the monopoly of specialism. I fear that some general as well as special practitioners are guilty of that crime, though perhaps a specialty lends itself more easily to the felony. In any case it is but a matter of degree in the extent of criminality, and it is greatly to be regretted that practitioners, general and special, are to be found lending themselves to such actions. The general practitioner is aggrieved if the specialist does not charge high fees, and unless he does assumes he seeks to take his patients out of his hands altogether. A solution of the question offers itself, viz., that it be no detriment to the specialist to take moderate fees. And this is probably what will result, that in all cases of difficulty and chronicity, whether among the poorer or the richer classes, the specialist should be consulted. To argue against specialism now is to argue against civilisation. The specialist with special practice must excel. Take one of the simplest of specialties—dentistry. Few departments, if any, are easier to attain a knowledge of, yet what proportion of dental work falls to the lot of the general compared with the special practitioner? There is a division of medicine in which, if in any, the general practitioner should equal the special. Yet in every town of adequate size specialists in midwifery are found. In the more difficult departments the specialisation is more accentuated. The advantage of specialism is that its practitioners have very much greater experience than the general practitioner, and even the general physician or surgeon. For one case of glaucoma, lupus, laryngeal tumour, or nasal polypus, &c., the general man sees, the special will see twenty or fifty or more. In the management of these he must attain to greater and more satisfactory knowledge. General practitioners, as their name implies, are intended to treat the generality of diseases; those which are unusual, tedious, or refractory they would do well to refer to the specialist.

I am, Sirs, yours truly,

Aug. 22nd, 1895. A SPECIALIST.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

The Corporation and the Mersey and Irwell Joint Committee.

IN THE LANCET of the 17th inst. the relations of the corporation to the joint committee are adverted to, and at the last meeting of the city council Alderman Thompson, chairman of the Rivers Committee, made some remarks on the same subject, saying that "the time had arrived when Manchester ought to be on its dignity as regards the joint committee." The precise bearing of that expression in relation to the pollution of the Irwell by Manchester sewage is not obvious. He alluded to the unpleasant position he had occupied in presiding over that committee (being its vice-chairman) when the Manchester effluent was being denounced, "but now that Sir John Hibbert had been relieved of Parliamentary duties and could take his place as chairman, he (the Alderman) could speak out." The Manchester effluent was said to be bad, but he added that Sir Henry Roscoe, in his report on twenty specimens of effluents from various places, described it as "slightly turbid, containing a little oxide of iron in suspension, and with a slightly tarry smell," while against this the effluents from various residential places were said to have a "sewage smell" and a "putrescent smell." This does not sound very dreadful, but it differs much from the description current some little time since. He went on to say: "Considering the amount of fæcal matter, market refuse, and refuse from dye-works and other places that had to be dealt with in Manchester, he thought they were entitled to praise for the effluent rather than blame." For the moment, perhaps, he did not bear in mind that this is only in part a water-carriage town, and that the market refuse and a good part of that from dye-works are solid, and therefore do not go into the sewers. Some time must elapse before the sewage arrangements of Manchester can be considered perfect, and the corporation cannot at present feel quite happy when the matter is discussed in the joint committee, though great efforts are being made to push on the various works. In the meantime the vice-chairman and his colleagues from the city council must be the victims of contending emotions—on the one side fired with zeal for purity of effluent, and on the other tempted to think that even virtue may be carried to excess. The composition of this joint committee is somewhat complex, but fairly representative of the interests involved. The County Councils of Lancashire and Cheshire send respectively eight and three members, Manchester and Salford six and two, while Bolton, Bury, Oldham, Rochdale, and Stockport send one each. Sir John Hibbert, the chairman of the Lancashire County Council, is also chairman of the Mersey and Irwell and of the Ribble joint committees.

Purchase of Chat Moss.

An important addition to the property of the corporation was announced at the last meeting of the council—viz., the purchase of Chat Moss, with an area of 2500 acres. The cost, *plus* law and other charges, was £147,631 4*s.* 11*d.* This is a large sum for it in these days of diminished land values, but the longer the delay the higher the price would be, so that without doubt the corporation has done wisely in

Digitized by Google

completing the purchase. The chairman of the Cleansing Committee thought that if there were no enlargement of the city area there would be ample accommodation for dealing with the refuse for fifty years to come. Carrington Moss, on the Cheshire side of the Mersey, is rapidly becoming converted, by the action of Manchester refuse, from an expanse of peat-bog into fertile agricultural land, producing luxuriant crops, and no doubt Chat Moss will gradually undergo the same change. Though Manchester is slowly becoming a watercloset town, many years must pass before the transformation is complete, and in the meantime restoration to the earth of what was originally taken from it ought to be a less wasteful proceeding than carrying fertilising material out to sea, as Salford is doing, and as some consider Manchester will be driven to do.

Bequests to Local Charities.

The sum of £47,000, free of legacy duty, has just been left to various local charities by the late Mr. Wm. Berry. The Royal Infirmary receives £10,000, the Ancoats Hospital and St. Mary's Hospital £5000 each, and £13,000 are divided among nine other hospitals. The total help, therefore, to the medical charities amounts to £33,000. In addition to this £14,000 are left to local philanthropic institutions, £2000 to the National Life-boat Institution, and £1000 each to Mr. Barnardo's Homes and the Society for the Prevention of Cruelty to Children. Mr. Berry was what is called a self-made man, having had no advantages of education or capital. His business career began by his making blacking on a small scale, with his own hands, and then taking it about to sell as he could. By industry, honesty, and the possession of the commercial aptitude found sometimes to a remarkable degree in men not otherwise intellectually distinguished, he gradually prospered and acquired a fortune nearly, if not quite, reaching half a million. He was a kindly, unostentatious man, who by reading had acquired a good deal of information, more or less perfectly assimilated, and it may be said to his credit that he never pretended to be other than one raised from the ranks.

Manchester Museum, Owens College.

The question of aid to the above museum came up at the last meeting of the council. The library committee recommended that a grant of £400 per annum be made, on condition that the Lancashire and Cheshire County Councils and the local district councils gave £800 a year. As an amendment it was proposed that the £400 should in any case be given. After some discussion it was decided to postpone the further consideration of the question till the members of the council had had the opportunity of seeing the museum. On Thursday and yesterday, therefore, they visited the College and were received by Mr. Edward Donner, chairman of the museum committee, Mr. Henry Wild, F.R.S., Mr. Thomas Ashton, LL.D., Mr. J. Cosmo Melvill, Dr. Leech, Professor Boyd Dawkins, and other gentlemen. Dr. Leech pointed out the importance of the museum to the public in several respects. It was, he said, a teaching museum, and not a mere agglomeration of curios. Lecturers from the whole of the city and the surrounding districts were accustomed to send their classes to verify by observation what they had been taught. Insects and other animals were brought to the museum that it might be ascertained whether they were likely to be harmful to cotton, wood, or crops. Associations concerned with self-education and literary and scientific societies came for entertainment and instruction. Much interest is also, in this district of coal mines, taken in the geological collection, so valuable in relation to the geology of the coal measures. Dr. Leech very properly emphasised the fact—not known as it should be—that the museum is open to the public every day without charge. The members of the council were very favourably impressed by what they saw and heard, and it is to be hoped that the corporation will come to the help of an institution so valuable to the city.

Death after Vaccination.

An inquest was held last week touching the death of a child said to have been due to vaccination. The mother said that up to the age of eleven weeks the child was healthy. "It"—the sex not being named—was then, June 12th, vaccinated from another child, together with six other infants. Nine days afterwards it had a "gathering" in the right ear and a sore on the foot. On July 8th it got worse, and the gentleman by whom it had been vaccinated prescribed for it. Another gentleman attended it for five weeks, but it got worse. There were running sores on the back of the head, side, and legs. After this a third medical man treated it until Aug. 11th, when it died, and he gave a certificate of death from blood poisoning. Mr. Jones, the public vaccinator for the Openshaw district, said he vaccinated the child, which was healthy, with lymph from another healthy child. In answer to the coroner he said "we have to vaccinate from arm to arm." The Government supplied lymph perhaps once in six months. The coroner said: "If there is to be compulsory vaccination it is the duty of the Government to supply lymph," and that he would not have his child vaccinated from another. Mr. J. Collier, F.R.C.S.Eng., who made a necropsy, said there were extensive ulcerations in various parts of the body. "The lungs were congested and there were signs about the heart and other internal organs of death from blood poisoning, which was, in fact, the cause of death. There were no signs of syphilis. ..... He was of opinion that something not medically clean had touched the wound and set up blood poisoning. He had seen the child from which the deceased was vaccinated and it was perfectly healthy." In reply to the jury, he said "vaccination was the indirect cause of the child's death, but some germ had got into the blood afterwards." Mr. Martin, medical officer of health for Gorton, said that when the child was brought to him it was suffering from general blood poisoning, not from syphilis. The disease had been communicated after vaccination. It is satisfactory to find that the jury returned a verdict to the effect that the child's death was due to blood poisoning following, but not due to, vaccination, and that no blame attached to Mr. Jones. As the *Manchester Courier* says: "Openshaw has been within an ace of furnishing anti-vaccinators with a trump card." It thinks it a pity that calf lymph is not supplied by the Government, and asks, "Why should public vaccinators be required to use a species of lymph which is under suspicion?"

Aug. 20th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

The Proposed Edinburgh City Hospital.

As I have already mentioned, the authorities in Edinburgh desire to erect a temporary hospital within a district which is under the Leith town council as governors of Trinity Hospital. The adjourned petition came up before the Leith Dean of Guild Court on Monday last. The Provost of Leith was in the chair, and he at once made a statement condemning and opposing the scheme, and pointing out that they had power to prevent the hospital being placed on the proposed site. The proceedings were somewhat animated and a tone of irritation ran through them. Leith is at present very sensitive and jealous of its big neighbour, for it evidently dreads absorption, and it knows that the most powerful lever for such a step is the advantage it might be to the public health. The application was almost precipitately hustled out of court.

The Holiday Season in Edinburgh.

Comparatively few of the senior members of the Royal Infirmary staff are in town at present, the work at the infirmary being largely done by the assistant staff of physicians and surgeons. Edinburgh as a city is so wholly given over to holiday-making that private practice is nearly at a standstill this month.

Professor Annandale.

Professor Annandale's numerous friends will be pleased to know that he is recovering. He has had a trying illness, and he has been much missed from his place in the lecture-room and the wards during the past months, but it is hoped and expected that the opening of the winter session will see him at his old post with his accustomed vigour.

Arbroath Infirmary.

At a meeting of the directors of the Arbroath Infirmary held this week the Arbroath local authority and the Arbroath district committee of the county council made a proposal that the infirmary should take charge of the epidemic hospital. The directors asked that each of the local authorities should pay £35 a year in addition to the charge for the patients. The local authorities declined these terms, so the proposal was abandoned.

Aberdeen University: the New Buildings at Marischal College.

The Mitchell block and other works at Marischal College are being pushed on apace, in order that the inauguration celebration in October may take place in a finished and splendid building. A grant was made at the last meeting of the University Court to enable alterations to be effected in the entrance and main staircase, and there new and rich decorations are being carried out. Inside the Graduation Hall the handsome design is already appearing through the mass of scaffolding. The granite tracery is completed and the stained glass windows now show clearly the arms and portraiture of men distinguished in the annals of the University. The erstwhile students' reading-room and the Wilson Museum are being largely transformed. Direct access can now be had to the tower without passing through the reading-room. Visitors can now ascend to the upper platform of the tower, a considerable distance above the "clock platform," and from this point a most commanding view of the city and neighbourhood is obtained. The inaugural celebration will take place on Oct. 22nd, 23rd, 24th, and 25th, and the following are the arrangements as regards academic costume. 1. Former graduates may appear either in plain dress or in the appropriate costume indicative of their faculty—viz., black gown and the special hood of their degree. In the case of doctors, whether of law, divinity, or medicine, it is optional to wear the black gown and distinctive hood, or to appear in the full-dress robe of doctors now sanctioned for important occasions, consisting of a scarlet gown with facings of the same silk as that which indicates in the hood the degree. In the latter case the separate hood is not required. 2. Graduates who are to receive the honorary degree in laws or in divinity may appear either in black gown and be invested with the appropriate hood after the capping, or in plain forenoon dress, and be invested with the full academic dress of doctors—viz., scarlet robe with distinctive silk facings. In either case the hood or robe will be provided beforehand by the recipient of the degree.

Aberdeen University: the New Appeal to the Public for Contributions for the Completion of the Extension Scheme.

The executive committee have decided to circulate a statement dealing with the financial aspect of the scheme, more or less historically and indicating the probable cost of the remaining portion of the scheme. The remaining works consist of the tower at the extremity of the north wing, the south wing and corresponding tower, central block, front railings and gates, ventilation, fittings, and the alteration of old buildings and agricultural department. The total estimated cost of these, including architect's fees &c. and the present deficiency on sites, works contracted for, &c., is £41,322.

Aberdeen University: Donation by a distinguished Medical Graduate.

Dr. Thomas Irvine Rowell, C.M.G., late principal civil medical officer to the Government of the Straits Settlements and formerly President of the Municipality of Singapore, has contributed the sum of £100 towards the extension fund. The letter intimating the subscription was addressed to his cousin, the Lord Provost of Aberdeen. It expressed the hope that the citizens and graduates would be stimulated and inspired by Dr. Mitchell's munificence to place the University Court in funds sufficient to complete the scheme. The publication of the letter in the Aberdeen papers has given somewhat of a fillip to the fund; but the Court still require £40,000, and a fresh appeal for subscriptions is to be issued. Dr. Rowell when a youth was first bursar at King's College, Aberdeen.

New Convalescent Hospital at Aberdeen.

The difficulties of the directors of the Royal Infirmary in procuring a suitable site are now over. They have found four acres of ground at Hillhead of Pitfodels, about four miles from the General Post Office. The site is near the high service reservoir, and arrangements have been made for laying pipes and obtaining water from the city supply. The ground lies high, but the exposure is good, and the one and a half acres of wood which will be included will afford a sheltered airing ground in hot weather.

Aberdeen Nursing Association.

It is hoped that a member of the Royal Family will open the forthcoming bazaar, the object of which is to provide funds for the alterations on the new home for the nurses and for other purposes of the association.

Aberdeen: Health of the City.

The following is the return of zymotic diseases notified to the medical officer of health for last week: Measles, 2; scarlet fever, 9; diphtheria, 1; typhoid fever, 2; whooping-cough, 32; erysipelas, 5; cholera infantum, 1; total cases, 52, being 24 fewer than in the preceding week.

Aug. 21st.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Health of Dublin.

IN view of the very large influx of visitors to Dublin for the coming Horse Show, to commence on the 27th inst., it is satisfactory to note that the recent reports of the Public Health Committee show the condition of the city and surrounding districts to be more than usually salubrious. Small-pox as an epidemic has practically disappeared, and there has recently been a marked decline in the reduced number of cases in hospital. The Registrar-General's recent report of the Pembroke district, in which the Royal Dublin Society's exhibition will be held, is most satisfactory and compares favourably with similar districts such as Rathmines, Kingstown, &c.

Poisoning in St. Stephen's Green.

Three children were admitted to Mercer's Hospital on the 13th inst. suffering from irritant poisoning caused by their having eaten some berries from a laburnum tree growing in St. Stephen's Green. But for the promptitude with which they were brought for treatment the consequences might have been fatal to one or all of them. They have now been discharged well, but their case is one of the many recorded in which virulently poisonous but ornamental plants growing in public gardens have caused serious danger. Among the commonest of these is the deadly nightshade (Atropa belladonna) and the English laburnum (Cytisus laburnum), and monkshood (Aconitum napellus).

Double Distal Ligature for Innominate Aneurysm.

A man aged forty-nine, suffering from a large and thin-walled innominate aneurysm which had produced dislocation forwards of the right clavicle, and which had defied the usual medical measures of treatment—viz., prolonged rest, iodide of potassium, &c.—is now under surgical treatment at the Mater Misericordiæ Hospital. His right subclavian and common carotid arteries were simultaneously ligatured three weeks ago, and both wounds have long since closed *per primam*. Consolidation has not, however, taken place in the aneurysm, but its pulsation has become much less strong, while its walls have become thickened by fibrinous deposit. The arteries of the patient's right arm are, moreover, pulseless. The distal operation for innominate aneurysm, which the writings of Mr. Barwell of London have done so much to popularise with surgeons, has been performed on three occasions only in Dublin—once by Mr. Conway Dwyer of Jervis-street Hospital and twice by Mr. Coppinger of the Mater Misericordiæ Hospital. The first two patients are now well and apparently cured of their disease, while the last, the most serious of the three, promises fairly.

Richmond District Lunatic Asylum.

A serious irregularity seems to have taken place recently at this institution during the absence on leave of the resident medical superintendent. According to the reports in the public papers, the body of a patient was left, owing to the neglect of some of the attendants, uninterred for nine days.

The Battle of the Clubs at Cork.

The Mayor has communicated with the profession in Cork requesting them to send six representatives to meet a similar number of delegates from the clubs for the purpose of discussing the questions in dispute with a view to arranging a compromise if possible, a result that the Mayor is particularly anxious should be arrived at. Accordingly the following gentlemen were selected to meet the Mayor and the club delegates—Dr. Hobart, Dr. E. Townsend, Dr. Corby, Dr. Magner, Dr. Giusani, and Mr. Lee. The first meeting was held in the municipal buildings, and lasted two hours. Though each side was to be at liberty to communicate with the bodies they represented, one of the club delegates suggested that no information should be given to the press except a brief statement by the Mayor. The Mayor observed his part of the compact

Digitized by Google

but a leading article appeared the following morning in a daily paper commenting on the conference in a manner which the profession considers unfair. A second meeting was held on Friday last, and an important decision arrived at. The club delegates announced that no arrangement could be come to unless the profession at Cork would undertake to meet in consultation the three medical men who since the commencement of the dispute have been acting for the clubs. The medical delegates replied that it would be quite impossible to accept such terms. They pointed out that the Cork medical men had made only fair and reasonable demands, and had only done so when they found medical practice in the city was being ruined by the club system, that the three medical men referred to had done all in their power to resist the demands of the profession, and under the circumstances the medical practitioners of Cork could not regard them as professional brethren. The fact was also emphasized that there are only five clubs vacant at present; that the three imported men hold the remainder, constituting the majority of the clubs; that the suggestion of the club delegates, if acted on, would mean that facilities should be given to those three men to remain in possession of the appointments which were resigned by the Cork medical men as a protest against the action of the clubs; and that the original club medical officers would be thereby precluded from ever getting back those appointments. The medical delegates considered it quite unnecessary to refer to the general body of the profession a proposition which would imply such a base betrayal of many of their colleagues. The Mayor then said he would request the three imported medical men to have an interview with him, and he would ascertain from them whether for purpose of facilitating a compromise they would be prepared to leave the city. To-day (Wednesday), at a further conference, the Mayor stated that the three imported medical men were not disposed to fall in with those views, and that they would not agree to any terms which would not imply their recognition by the Cork profession. The Mayor expressed great regret that his efforts to bring about a friendly understanding between the Cork profession and the clubs had not been more successful. The assembled delegates passed a vote of thanks to the Mayor, and the proceedings terminated. Acts, not words, has been the motto of the Cork medical practitioners, and though all the correspondence and speech-making have been the undisputed prerogatives of the clubs it is notable how steadily public opinion has veered round to regard with favour the claims put forward by the Cork profession. As an instance I may mention that early last week, when the Mayor's conference was first proposed, one of the local papers which previously could discover no redeeming feature in the opposition of the medical men to the encroachments of the clubs, published in a leading article the following sentiments: "It is easy to understand that when clubs combine to be granted lower fees than the members would be charged individually, the unfortunate practitioner may find that with very much more than an eight hours' day to work a 'living wage' could not be earned. ..... Each side will be the gainer by a fair settlement, and, dealing as we are with honourable and intelligent men, we are practically certain that the result of the present negotiations will be in all respects satisfactory."

The Legal Proceedings by a Member of a Cork Club for Sick Pay.

After a patient hearing the magistrates unanimously decided on giving a decree against the secretary of the Irish National Foresters for the full amount of sick pay claimed by Mr. Carroll, one of their members. I sent you a brief account of the case in my notes last week. Mr. Blake, solicitor for the secretary, asked to have a case stated for the superior courts. Mr. Healy, solicitor for the plaintiff, complained of the hardship of compelling his client to fight the case in the superior courts. It was eventually decided that the case should be brought on appeal before the Recorder. In the course of the proceedings one of the medical men imported by the Cork clubs was made to admit that he possessed no medical qualification; but it is difficult to see how this fact was relevant to the case.

The Belfast Union.

The half-yearly report of Mr. Agnew, Local Government Board inspector, on the Belfast Union has just been published. He thinks the condition of the separation department requires the urgent attention of the guardians, in order not only that more room may be afforded to the mothers and their children, but also that persons suffering from venereal disease may be removed therefrom and be afforded separate accommodation. He recommends that the sewer at the north end of the premises, which still constitutes a nuisance, should be done away with forthwith by the corporation. He recommends also that steps should be taken to put the yards into proper order and that some efforts should be made to have the boys taught handicrafts. The number of inmates classified as insane was on the day of the inspector's visit 439, and for their accommodation the guardians have provided a large and commodious detached building at a cost of £14,000, and they are, in addition, now expending a sum of almost £2000 in providing apartments for the resident medical officer, nurses, and warders, and also increased dining-hall accommodation, together with additional and improved baths, lavatories, and closets. The inspector recommends the appropriation of a portion of the adjoining ground as a recreation place. The report is favourable to the Belfast Union. In reference to the Fever Hospital, the inspector states that the accommodation is ample, and the nursing, dietary, sanitation, and ventilation are satisfactory.

Science Research Scholarship.

On the recommendation of the Council of Queen's College, Belfast, Mr. William Hanna, M.A., M.B., has been appointed by Her Majesty's Commissioners for the Exhibition of 1851 to a Science Research Scholarship for the year 1895. The exhibition is of the value of £150 and is tenable for two years.

The Proposed Asylum at Purdysburn.

At the monthly meeting of the board of governors of the Belfast Asylum, held on Aug. 12th, in reply to some questions Dr. Merrick, the medical superintendent, stated that the Board of Control considered that Purdysburn would be a better place than Belfast for acute cases, while the governors were agreed that they should keep Belfast as a going concern and send chronic cases to Purdysburn. There would seem to be considerable difference of opinion as to the extent of building to be erected at Purdysburn, and this probably arises from the constitution of the board. Some of the governors are appointed by the Lord Lieutenant, some by the grand jury of county Antrim, and some by the Belfast corporation, while the united body of governors have to act in conjunction with the Board of Control in Dublin. The question of the probable expense of the new asylum is a most important element. Some of the governors thought a building to accommodate, as a hospital, 250 patients would be sufficient, while others were in favour of erecting a complete asylum for between 800 and 1000 inmates. The Board of Control in Dublin approved of the latter plan, and accordingly a resolution was passed at a previous meeting that architects are to be invited to send in designs and specifications for a large and complete building to accommodate 800 patients, and prizes of £100, £75, and £50 are to be given to the designs awarded first, second, and third places. At the meeting on Aug. 12th some of the governors again raised the question that they were not pulling in exact harmony with the city corporation, who had expressed the opinion that they would not build a complete hospital by getting plans which only indicated that they wanted a complete asylum. A prolonged discussion ensued, in which the feeling of the governors was that, when the ratepayers were consulted through the city corporation, two schemes should be submitted: first, a plan for a small building to accommodate, say, 250 patients; and, secondly, a design for a complete asylum, with the full cost and advantages of each plan. Ultimately the following resolution, moved by Mr. Harrison, B.L. (a member of the city corporation), and seconded by Professor Cuming, M.D., was passed unanimously: "That the Board of Control be informed that it was the intention and the desire of the board of governors that separate plans be furnished for a detached asylum building for chronic cases, capable of holding at present 250 patients, and of afterwards being used as an acute hospital."

Garvagh Dispensary

At a special meeting of the Garvagh Dispensary committee Dr. Adams was unanimously appointed medical officer of the district in succession to Dr. McNeary (resigned), and it was also agreed to recommend the Coleraine board of guardians to fix the salary at £115 per annum.

Rabies in the Downpatrick District.

At the weekly meeting of the Downpatrick board of guardians, held on Aug. 17th, a letter was read from the veterinary department, Dublin, regretting that the guardians had declined to make regulations for the muzzling of dogs in the union, and again enjoining upon them, in view of the continued recurrence of rabies, to exercise the powers conferred upon them by Article 10 of the Rabies Order of this year. The guardians, however, declined to take action, one of them, Lord de Ros, alone dissenting.

The Consumption Hospital, Belfast.

One of the Belfast merchant princes, Mr. Forster Green, a member of the Society of Friends, has purchased, at the cost of several thousand pounds, Fortbreda, a most beautiful residence with commodious grounds in an elevated position in one of the most healthy districts in Belfast, and intends to present it to the committee of the Hospital for Consumption in Belfast. It will be an admirable place for the purpose. This is only one of very many acts of charity done by Mr. Forster Green.

Aug. 20th.

Obituary.

GEORGE STEELE, M.B., C.M. GLASG.

INTELLIGENCE, energy, and amiability, combined with sound professional attainments and a consuming love of his fellow man—such were the characteristics of this young missionary explorer, who succumbed to fever in Ngoniland on June 24th. Dr. George Steele was born in the Bridgetown Division of Glasgow, and, with a view to the practice of medicine, studied at the University, and in due course graduated M.B., C.M. Shortly thereafter he resolved to devote his abilities and acquirements to the moral reclamation of the savage tribes of Central Africa and, strongly aided in his resolve by the Edinburgh promoters of medical missions—conspicuous among whom may be mentioned his friend, Mr. John James Cowan—he placed his services at the disposal of the Livingstonia Committee of the Free Church of Scotland, who, six years ago, sent him to assist Dr. Elmslie of Aberdeen in reclaiming the warrior Zulus to civilisation. Such interest had he inspired in his undertaking that the many friends whom he had made in his academic and post-graduate days assembled *en masse* at the Central Railway Station to see him off and bid him God-speed. Arrived at his destination, his first post was in the Ngoni country, a healthy plateau occupied by the tribe of that name above Bandawé on the western shore of Lake Nyassa. In this region he lived and laboured, doing solid and even brilliant work for many a "noble savage," till the regulation period before furlough found him much in need of rest and change. This well-earned holiday was to have begun on May-day of the present year, but, from causes not yet explained, he postponed his departure. A missionary tour in Australia, devised to arouse colonial interest in Central African work, with a subsequent visit to Scotland in contemplation, was his programme. But it was destined never to be carried out. His much-tried constitution failed to rally under his latest febrile seizure, and, as announced by telegram, he died on June 24th.

Scotland, from Mungo Park downwards, has been honourably distinguished through her medical sons in the field of African exploration, and the great career of David Livingstone has proved to many a young compatriot a powerful incentive to "go and do likewise." Dr. Steele was one of these, and the fate that befel him has been but too typical of what awaits the "missionary hero" in the Dark Continent. Shortly before him, there died in the same region and under similar circumstances Mr. Monteith Fotheringham, to whose ability and energy the African Lakes Corporation is so deeply indebted. Life in the more salubrious uplands in his case, as in Dr. Steele's, was all too inadequate to countervail the fevers contracted on visits, however occasional, to the lower levels around Lake Nyassa and the valleys of Shiré and Zambesi. Five years' residence, even in the healthier hill country, is as much, indeed, as has been found compatible with safety, and so the Livingstonia Committee has made it a rule that its emissaries may go on furlough after their first three years of work. But prudence has seldom a place in the vocabulary of the missionary enthusiast, and so Dr. Steele's exemplar must be added to many others among his profession and vocation, of the self-sacrifice that knows no fear and of the love that is stronger than death.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Kurt Schimmelbusch, for many years assistant to Professor Bergmann in the Berlin Surgical Clinic, after a month's illness, at the age of thirty-five. At the conclusion of his student's course he acted for a time as assistant to Professor Eberth of Halle, with whom he carried out various anatomical, pathological, and bacteriological researches, the best known of which were upon thrombosis and embolism. Afterwards he decided to devote himself to surgery, and became assistant to Dr. Bardenheuer in Cologne, later going to Berlin, where he was looked upon as one of the most rising surgeons of the day.—Dr. Felix Hoppe-Seyler, Professor of Physiological Chemistry in the University of Strasburg, at the age of seventy, from an apoplectic attack, at his summer residence on the Bodensee.

AUSTRALASIAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.—The seventh session of the above association will be held in Sydney from Jan. 3rd to 10th, 1896, under the Presidency of A. Liversidge, M.A., F.R.S., Professor of Chemistry, University of Sydney. The Presidents and Secretaries of the Sections are as follows:—*Astronomy, Mathematics, and Physics:* R. L. J. Ellery, C.M.G., F.R.S., Government Astronomer, Victoria, President; R. Threlfall, M.A., Professor of Physics, and J. Arthur Pollock, B.Sc., Demonstrator in Physics, Sydney University, Secretaries. *Chemistry:* T. C. Cloud, A.R.S.M., F.C.S., Manager, Wallaroo Copper Works, South Australia, President; W. M. Hamlet, F.C.S., F.I.C., Government Analyst, New South Wales, Secretary. *Geology and Mineralogy:* Captain F. W. Hutton, M.A., F.R.S., F.G.S., Director of Canterbury Museum and Lecturer in Geology, Christ Church, New Zealand, President; T. W. E. David, B.A., F.G.S., Professor of Geology and Physical Geography, Sydney University, and E. F. Pittman, A.R.S.M., F.G.S., L.S., Government Geologist, New South Wales, and Lecturer in Mining, Sydney University, Secretaries. *Biology:* T. J. Parker, B.Sc., F.R.S., Professor of Biology, Otago University, Dunedin, New Zealand, President; W. A. Haswell, M.A., D.Sc., F.L.S., Professor of Biology, Sydney University, and J. H. Maiden, F.C.S., F.L.S., Curator, Technological Museum, Sydney, and Superintendent of Technical Education, New South Wales, Secretaries. *Geography:* H. S. W. Crummer, Secretary of the Royal Geographical Society of Australasia, New South Wales Branch, Secretary. *Ethnology and Anthropology:* A. W. Howitt, F.G.S., Secretary for Mines, Victoria, President; John Fraser, B.A., LL.D., Sydney, Secretary. *Economic Science and Agriculture:* R. M. Johnston, F.L.S., Government Statistician, Tasmania, President; Walter Scott, M.A., Professor of Greek, Sydney University, and F. B. Guthrie, F.C.S., Consulting Chemist to the Department of Agriculture, New South Wales, Secretaries. *Engineering and Architecture:* H. C. Stanley, M.I.C.E., Chief Engineer, Southern and Western Railway Lines, Queensland, President; J. W. Grimshaw, M.I.C.E., M.I.M.E., &c., Supervising Engineer, Harbours and Rivers Department, New South Wales, Secretary. *Sanitary Science and Hygiene:* Hon. Allan Campbell, M.L.C., L.R.C.P., South Australia, President; J. Ashburton Thompson, M.D., Chief Medical Inspector, Board of Health, New South Wales, Secretary. *Mental Science and Education:* John Shirley, B. Sc., District Inspector of Schools, Brisbane, Queensland, President; Francis Anderson, M.A., Professor of Logic and Mental Philosophy, Sydney University, Secretary. Communications and papers for the meeting, or inquiries, may be addressed to the Permanent Honorary Secretary, the Chemical Laboratory, the University, Sydney, New South Wales.

THE

BRITISH MEDICAL ASSOCIATION.

MEETING IN LONDON.

THE SECTIONS.

PUBLIC MEDICINE.

THURSDAY, AUG. 1ST.

The Prevention of Milk Epidemics.

Dr. KENWOOD, medical officer of health of Stoke Newington and Finchley, opened a discussion on this subject. By means of a circular note addressed to all the medical officers of health of areas situated within the metropolis and the home counties of Middlesex, Surrey, Essex, Kent, Hertfordshire, Buckinghamshire, and Berkshire, he had collected the facts in reference to those milk epidemics that had had their origin in diseased cows in the years 1893 and 1894. In each of his two districts (Stoke Newington and Finchley) there had been such an epidemic during the past year, and it was abundantly clear in both cases that the community was practically unprotected from such visitations; indeed, a sufficient answer to those who might contend that the steps taken at the present day were satisfactory was found in the reply that such outbreaks were not prevented, that they occurred in large numbers in this country, and that they showed a tendency to increase. It was high time, with these epidemics constantly cropping up, that something more should be done to prevent their recurrence. Practically, present action was restricted to preventing the further spread of the outbreak after it had already worked a varying amount of harm, but it was easily practicable to proceed upon lines of true prevention that would aim at removing the possibility of future outbreak. The necessity for further steps was a growing one for the reasons: 1. That the cowkeepers were becoming less and less generally the milk retailers, and they were not, therefore, affected to anything like the same extent as the latter by the consequences of a milk epidemic; moreover, cowkeepers did not (and, it seemed, would not) recognise the necessity of excluding the milk of cows suffering from those transitory, often slight, and generally obscure ailments that might furnish an infective quality to the milk. 2. The establishment of large companies with large and irregular areas of distribution was gradually displacing the man with a small and circumscribed area to supply, and the result was a much greater difficulty in tracing the origin of a milk epidemic. He then proceeded to discuss the powers that had been granted to local authorities and the reasons of their failure. Careful examination of all milch cows at short intervals, preferably once a week, the prompt isolation of those animals likely to furnish infective milk, and the adoption of means that would deter the cowkeeper from mixing the milk of such animals with other milk were, in his opinion, the only ways of dealing with the difficulty. He then dwelt on the necessity for the appointment of special inspectors of cows and cowsheds, discussed the qualifications of such inspectors, and recommended their appointment in some cases by neighbouring authorities in combination. The necessity for such inspectors to notify at once all cases of suspicious disease in cows to the medical officer of health was pointed out. The conditions in cows which might render their milk noxious to human beings were enumerated, and the symptoms that would warrant the inspector in requiring isolation were stated. Suggested rules for the guidance of such inspectors were given.

Brigade-Surgeon-Lieutenant-Colonel PRINGLE said he believed a great deal of the mischief with regard to milk contamination was due to the state of the places where it was retailed. Some shopkeepers who kept milk also sold cheese, bacon, and other things, and in many cases these commodities were in a varying state of decomposition.

Dr. BOND said he had never been able to directly trace a case of outbreak of disease to contaminated milk in his district. At the same time he heartily agreed with Dr. Kenwood's scheme, if practicable, but he thought there would be considerable difficulty in carrying it out.

Vital Statistics of Diphtheria in London, 1891–95.

Dr. F. A. DIXEY, Fellow of Wadham College, Oxford, read an interesting paper on this subject. He said:—The remarkable rise in the number of deaths attributed to diphtheria during the last few years in London has attracted much attention and has given occasion to many valuable memoirs which have largely increased our knowledge of the subject. In the course of the following remarks I propose to examine the recent progress of the disease in London from the statistical side, making chief use of the information contained in the weekly returns of the Registrar-General.

1. *The general course of diphtheria in London, 1891–95.*—The history of fatal diphtheria in London since the beginning of 1891 is shown in Table I., which gives for each week the actual number of deaths returned as due to "diphtheria," together with the average number of deaths attributed to the same cause for the corresponding week of the last ten years, corrected for increase of population.

TABLE I.—*London, 1891–95: Weekly Deaths from Diphtheria, with Corrected Means for Ten Years of the Corresponding Weeks.*

Weeks.	1891.		1892.		1893.		1894.		1895.	
	Deaths.	Corrected mean (10 years).	Deaths.	Corrected mean (10 years).	Deaths.	Corrected mean (10 years).	Deaths.	Corrected mean (10 years).	Deaths.	Corrected mean (10 years).

It will be seen that the number of deaths, though somewhat above the average for the greater part of 1891, had towards the end of the year sunk almost to the normal level. Soon after the beginning of 1892, however, a gradual rise takes place, which, with some considerable fluctuations, is, on the whole, steadily maintained throughout 1892 and 1893, until it culminates in the second week of November in the latter year, when the deaths attributed to diphtheria reached the unexampled total of 103. From this point a descent begins, at first rapid, afterwards more gradual, until finally, in the closing week of 1894, the number of recorded deaths once more coincides with the normal, from which it has not since greatly deviated.

2. *The seasonal prevalence of diphtheria in the years 1891-95.*—The ordinary seasonal relations of diphtheria are well known, having been worked out for London and New York by Sir A. Mitchell and Dr. Buchan in their admirable papers entitled "The Influence of Weather on Mortality from Different Diseases."[1] These authors have shown, from a consideration of the Registrar-General's weekly returns for sixteen years, that the deaths from diphtheria in London rise above the average in the beginning of September and remain above it till the beginning of March. The seasonal prevalence in New York is much the same as in London, except that the rise takes place about a month later and the range between maximum and minimum is of greater extent. They add that in New York the character of the seasonal curve remains fairly constant from year to year notwithstanding much fluctuation in the number of deaths. Looking at the London mortality curve for 1891 we see that the usual seasonal features are on the whole fairly well maintained, in spite of the somewhat exceptional mortality in the earlier part of the year. In 1892 the general rise begins, the most marked step occurring at the end of April and beginning of May, and to the high level of mortality thus abnormally reached and maintained the usual autumn exacerbation appears to be superadded. The curve for 1893 is a very fluctuating one, but in spite of the great variation of numbers from week to week and the general upward tendency of the curve the autumnal invasion is again well marked and of greater value, both absolutely and relatively, than in any previous year. In 1894, however, we find an altered state of things. With the high mortality of November, 1893, the disease seems to have in great measure spent its force; and a downward tendency begins which by the beginning of June brings the deaths to within ten of the corrected average. Here another rise seems to be starting, but it never becomes fully developed; and although September, as usual, shows a considerable increase in the number of deaths, the accustomed heavy mortality of the end of the year is altogether missing. The curve for 1895 has not as yet shown any marked elevation; a slight upward tendency, however, has been in progress since April, the further development of which it will be interesting to watch.

3. *Diphtheria and school attendance.*—In his excellent Annual Report of the Medical Officer of Health of the Administrative County of London, 1893, and more recently in his Presidential Address to the Epidemiological Society in 1894, Mr. Shirley Murphy has adduced much reason for thinking that the increased prevalence of diphtheria in this country is at least partly due to the operation of the Elementary Education Act of 1870. This conclusion, based by him mainly on the observed facts of age incidence of diphtheria, derives additional support from a consideration of the tables before us. The fall during the summer holidays in August and the rise corresponding to the reassembling of the schools in September are plainly shown by the curves of weekly deaths in every case; though, as Mr. Shirley Murphy notes, the August fall is less conspicuous in 1892 than in other years.

4. *Diphtheria and "croup."*—I now turn to the question of the relation between diphtheria and what appears in the Registrar-General's returns as "croup." Dr. Longstaff[2] cites with approval the opinion of Dr. Whitelegge "that there is no such disease as croup"; and it has long been admitted on all hands that a great deal of "croup" is actually diphtheria. In Table II. I have given the figures for "croup" corresponding to those in Table I. for diphtheria, and the same data are presented in graphic form by Wall Diagram 3.

The facts thus disclosed appear to me to make in favour of the view that, at least in past years, "croup" has robbed diphtheria of many deaths that were its due. While diphtheria has been rising, croup, we see, has been falling in a way more suggestive of altering diagnosis than of real diminution of disease.

5. *Effect of the antitoxin treatment.*—The last point which I shall here deal with is the diminution in mortality which has become apparent since the spring of 1894. The average weekly number of deaths from diphtheria for the whole year, which rose from 26·2 in 1891 to 36·2 in 1892, and to 62·8 in 1893, fell in 1894 to 51·4, and for the first half of the present year to 33·5. It is evident that from some quarter fatal diphtheria has received a check. This is not to be explained by any diminished occurrence of the disease, for it has remained, on the whole, as prevalent as ever. Evidence of this is furnished by Table III., with its accompanying diagram (4), which give the weekly number of admissions and cases under treatment for diphtheria in the Metropolitan Asylums and London Fever Hospitals since the beginning of 1893.

52	283	43	521	75	—	—

I am aware that these figures form only a rough measurement of the prevalence of disease; for, in addition to the fact that, to quote the Registrar-General's weekly returns, "in a considerable proportion of cases the diagnosis sent on admission is found, after sojourn in the hospital, to have been erroneous," it is also true that the proportion of hospital admissions to total cases notified is a variable one, ranging, for instance, in the cases of the hospitals of the Metropolitan Asylums Board, for the four years 1890–93, from 15 per cent. in 1890 to 25 per cent. in 1892;[3] moreover, it must be remembered, as has been specially pointed out by Dr. Whitelegge, that a period of great prevalence of a disease is by no means necessarily one of great case mortality. Still, when every allowance has been made for these sources of error, it must be granted to be a striking fact that the prevalence of diphtheria from the middle of 1894 up to the present date is out of all proportion to the number of fatal cases. Now, the antitoxin treatment of diphtheria began to be employed in this country in June, 1894, and by the end of the year it was in fairly full operation. It is, I think, an inference well warranted by the facts of the case that this method of treatment was last year instrumental in preventing the usual autumnal rise in the number of fatal cases, and has helped during 1895 in keeping down the diphtheria mortality in spite of the large amount of the disease still present in the metropolis.

[3] See Annual Report of Medical Officer of Health of London, 1893: Diphtheria, Diagram XI.

FRIDAY, AUG. 2ND.

Security of Tenure of Medical Officers of Health.

On Friday the concluding meeting of this Section was held, when Dr. COLLINGRIDGE occupied the chair.

At the commencement of the proceedings Professor G. VAN OVERBEEK DE MEYER invited the members of the Section to a "Conférence Internationale concernant les Services Sanitaires des Chemins de Fer et de la Navigation," shortly to be held at Amsterdam, the matters to be discussed being the personal fitness of the officials, the organisation of the medical service, and the hygienic interests of officials and travellers.

Dr. WHITELEGGE then introduced a discussion on the Insecurity of Tenure of Extra-Metropolitan Medical Officers of Health under the Public Health Act of 1895.

Dr. CARROLL, Dr. MANLEY, Dr. GRAHAM, Dr. MAESDEN, Brigade-Surgeon-Lieutenant-Colonel PRINGLE, Dr. SLADE KING, Dr. GROVES, Dr. CAMERON, Dr. BARWISE, Dr. OGILVIE GRANT, Dr. BOND, and Dr. WILLOUGHBY took part in the discussion, which concluded with the passing of the following resolution: "That this Section desires to reiterate the opinion which has been expressed at previous meetings of the Association that the interests of the public, no less than the just demands of medical officers of health, require that the same security of tenure which is enjoyed by medical officers of health in the metropolis and Scotch counties and by Poor-law medical officers should be conceded to provincial medical officers of health, and requests the Parliamentary Bills Committee to take such steps as may seem expedient to bring this matter under the notice of the Local Government Board."

Dr. SPOTTISWOODE CAMERON read a paper on the Destruction of Town Refuse, and, some other papers being taken as read, the business of the Section concluded.

PATHOLOGY.

THURSDAY, AUG. 1ST.

Pernicious Anæmia.

Dr. HUNTER opened a discussion upon Pernicious Anæmia with a paper in which he reviewed the present knowledge of the subject. He concluded that pernicious anæmia was a special disease apart from the other forms of anæmia, because the latter (such as occur in cancer and other diseases) do not show the same pathological changes in the blood that are met with in this form; because the extreme degree of blood change is always associated with marked pathological changes in the liver, kidney, and spleen such as are not found in traumatic and other anæmias. In refuting Dr. Stockman's views, that the main difference between pernicious anæmia and other forms of anæmia lay in the presence of hæmorrhages in the former and not in the latter, he said that he had failed to produce pigment deposits in the liver by injecting large quantities of blood into the peritoneal cavity of rabbits, and further that in his experience hæmorrhages in pernicious anæmia were very rare except into the retina and meningeal membranes.

Dr. COPEMAN expressed his opinion that pathological urobilin only occurred in those cases of pernicious anæmia associated with high temperature, and he thought that there were other cases in which just as profound changes occurred in the blood without the deposition of pigment in the liver.

Dr. GIBSON and Dr. STOCKMAN joined in the discussion, and Dr. HUNTER replied.

Owing to the time of the Section having been fully occupied with these discussions, the following papers were taken as read:—

Dr. MACFADYEN on the Formation of Methyl Mercaptan in the Body and its Production by Bacteria.

Mr. P. FURNIVALL on Acromegaly.

FRIDAY, AUG. 2ND.

Lymphadenoma and its Relation to other Morbid Growths.

The discussion upon this subject was opened by Mr. W. G. SPENCER, assistant surgeon to Westminster Hospital. Lymphadenoma, he said, is a suitable term for those affections the various forms of which have one feature in common—viz., a growth of lymphadenoid tissue closely resembling in structure that of lymphatic gland. In the present state of our knowledge it is better to rest content

Digitized by Google

with some general classification such as can be inferred from clinical facts and to use as few names as possible. It appears to me that the attention of this meeting may most usefully be directed towards a consideration of the causation of lymphadenoma, and as experimental data are wanting the subject of causation must necessarily be considered chiefly from a clinical standpoint. If we do this we may take as a guide at the start the analogy of tubercle, and distinguish a local disease under the head of lymphadenoma from a general affection, lymphadenomatosis, the latter being related to the former perhaps as general tuberculosis to a local mass of tubercle. Of local lymphadenoma we may further mark out two types—one simple lymphadenoma, in which the cause is more or less continuously acting upon the lymphadenoid tissue from the surface of the mucous membrane or skin, whereas in the more malignant form there is a lack of evidence as to the external source of the irritation; but, on the other hand, an essential proclivity on the part of the cells to proliferate, the cause of which must be within the tumour itself.

Simple Lymphadenoma. — The term lymphoma, since it includes no reference to *lymphatic gland*, requires qualification when used. Simple lymphadenoma forms a strictly local overgrowth of lymphadenoid tissue kept up by some cause acting from without, the growth ceasing when the cause ceases to act.

[Mr. SPENCER here gave instances of various irritations which cause simple enlargement of lymphatic glands. He continued:]

Malignant Lymphadenoma.—(The name Lymphosarcoma tends to connect the affection with sarcomas of lymph glands which differ widely from it in character.) In malignant lymphadenoma we have a factor distinct from the local irritation to which we ascribe the simple form, for in it there is the tendency on the part of the cells to proliferate indefinitely. The connective tissue cells of the gland capsule and septa likewise take part to some extent in the growth. We fail to find, at any rate after the earliest stages, any source of irritation sufficient, acting simply from without, to keep up the continued and indefinite multiplication of the cells. The cause of this continued multiplication of cells must therefore be within the tumour. In these respects malignant lymphadenoma resembles sarcoma, but in other points they are unlike. Malignant lymphadenoma does not infiltrate neighbouring structures, exercising its influence by compression. It can be shelled out, as it separates easily from the surrounding tissues. Organs such as the spleen or kidney retain their shape even when greatly enlarged. Tubes such as the œsophagus, intestine, or bloodvessels are surrounded by the growth without the lumen being narrowed. The cell elements show a remarkably long life, and ulceration and degeneration do not occur.

[Mr. SPENCER pointed out the differences between this disease and true sarcoma, and referred to the value of arsenic in treatment. He continued:]

Lymphadenomatosis.—There is clearly some *general* affection which attacks lymphadenoid tissue wherever found. Great variations are met with in different cases, both as regards the severity of the attack, in the incidence upon the several parts, together with the variations which happen in the course of any single case. Hence a number of divisions have arisen, each named after one prominent symptom. The spleen, the lymphatic glands, the bone marrow, lymphadenoid tissue around the alimentary canal or in the subcutaneous tissue—one or more of these structures may be found involved in a general disease accompanied by anæmia, cachexia, hæmorrhages, intermittent irregular fever, and increase of white blood cells. "Lymphatic cachexia," "Anæmia splenica vel lymphatica," "Splenic, lymphatic or myelogenic leucocythæmia," "Hodgkin's disease," "Multiple lymphosarcoma,"—these and other names have been used, just as a number of names have been employed in the past for tuberculosis. But it tends to promote confusion if one of the symptoms of the general malady be thus elevated to the rank of a special disease. As illustrating this we may take the word "Leucocythæmia," or "Leukæmia."

[Mr. SPENCER here referred to the various ways in which an increase of leucocytes may be brought about, and the difficulty of defining sharply any one form of lymphadenomatosis. He continued:]

Leucocythemia should, therefore, be looked upon as one symptom among others of a general disease. A more satisfactory plan would be an attempt to divide lymphadenomatosis according to its several modes of origin and the various ways by which the hypothetical virus may enter. In one group the cause of the disease appears to enter by the alimentary canal. Children suffer from anæmia, cachexia, hæmorrhages, irregular fevers, enlarged intestinal lymph follicles, spleen or retro-peritoneal glands with or without an increase of white cells. Cases of this kind are very numerous; one of these conditions may alone be present, or in combination with others, or all may coexist. The nature of this cause and its connexion with other general conditions, such as intestinal catarrh, inherited syphilis, tuberculosis, and rickets, forms a subject of great practical importance. Again, young men and boys—e.g., army recruits or young prisoners—are subject to sudden attacks in which the mediastinal glands are affected, either those in connexion with the thymus or behind the lungs. The disease is often attributed to cold, damp, and foul air. Does the poison in such cases enter by the lungs? Some of the cases are most acute; in one reported by Guttmann a boy died four and a half days after the first sign of illness, the immediate cause of death being cerebral hæmorrhage, but there was also a general enlargement of lymphadenoid tissue. In some cases an infectious disease precedes the outbreak. Dr. Hale White allows me to mention an acute case commencing in a previously healthy young man after influenza. Some forms suggest a virulent infection, but the evidence as to a transfer of this infection is negative. The only exception which has been brought forward is a case under Obratzow, in which a clinical assistant who helped to plug the nostrils and examine the urine and fæces of an acute case was attacked in a similar manner and died a month after. Other probably mere coincidences have been reported in which an injury in the region of the spleen or to the bones preceded the illness. It is very difficult frequently to distinguish such cases from tuberculosis. Indeed, some appear to be instances of a mixed infection—e.g., caseation in some glands, with adenomatous enlargement, especially of the spleen, which is of course seldom attacked by tubercle except in children. In the absence of exact knowledge it is impossible to discuss the relation between the infection and the resistance on the part of the individual—the relation between the seed and the soil. But by the light of analogy we may be assured that individual differences in resistance may originate many varieties from one and the same kind of infection. If we arrange the facts gleaned from the bedside in some general way, according to the probable mode of entry of the poison, we shall be ready to receive the new light which will doubtless soon be thrown upon lymphadenoma by biological and chemical researches. The experimental work on this subject is as yet merely in a laboratory stage, and the results hitherto obtained, interesting and extremely suggestive as they are, indicate the need for further work and the direction such work should take. Micro-organisms have been found in the growths, leucocytosis and anæmia have been produced by the injection of substances into the blood of animals, and clinical observations on the administration of materials obtained from the thyroid, thymus, spleen, and bone-marrow are going on. Some amount of mutual contradiction and of negative results inevitably take place in the earliest stages of an experimental research, and this prevents for the present any formation of an opinion upon the matter.

Mr. J. JACKSON CLARKE opened the discussion on the paper. He thought that no distinction could be made between lympho-sarcoma, Hodgkin's disease, and lymphadenoma. His experience of the use of arsenic in this disease was that it was only of temporary benefit, and he thought that many of the cases of lymphadenoma eventually went on to typical sarcomatous infiltration. Infiltration of the skin he regarded as a help in the diagnosis, especially in the case of deeper-seated mediastinal growths. In one case of lymphadenoma which he had seen the simple enlargement became eventually tuberculous, and finally a condition of pyæmia was set up. In those cases where cocci are found they are superadded and are evidence of the pyæmic condition of the patient. In leucocythæmia he had noticed lymphomatous growths in various organs, and he hesitated to mark these off as distinct from lympho-sarcoma. He drew attention to the occurrence of lympho-sarcoma in connexion with gout and osteo-arthritis; in the latter the bone-marrow shows small nodules of lympho-sarcomatous infiltration.

Dr. R. MURRAY LESLIE was in favour of the hypothesis that lymphadenoma was organismal in nature. He thought

Digitized by Google

considerable light was thrown on the pathology of the condition by a careful study of aberrant forms and allied diseases. He described forms to show that one or more, or all, the lymphoid structures may become involved in different ways, and also that there is a close relationship existing between lymphadenoma and such diseases as leukæmia and splenic anæmia. The number of leucocytes and hæmocytes depend on the relative involvement of blood-destroying structures. Dr. Leslie was of opinion that a study of the pathology of such cases would tend greatly to clear up our knowledge of hæmatogenesis and hæmatolysis. He brought forward the following points in favour of the hypothesis of organismal origin: (1) certain cases seem to owe their origin to exposure to foul air; (2) micrococci and other organisms have been found in the affected structures; (3) the close analogy which exists between this and tuberculosis and other organismal diseases; (4) affection of the cervical glands would point to infection by the mouth, of the mediastinal glands by the lungs, and of the mesenteric glands and Peyer's patches by the alimentary canal; (5) pyrexia and night sweats are present, as in other organismal diseases; and (6) the beneficial effects of arsenic are probably to be attributed to its germicidal action and are comparable with the action of mercury in syphilis. For these and other reasons he would class lymphadenoma in the great group of granulomata, of which syphilis, tubercle, and leprosy are examples.

Dr. G. N. PITT, in a paper, noticed the affection of bronchial glands following on chronic bronchial irritation. He distinguished true lymphadenoma as consisting of an adenoid overgrowth limited to adenoid tissue, which never fungates or infiltrates, and which destroys only by pressure on vital structures. He had seen tubercle and lymphadenoma associated together in the post-mortem room, and he thought that in the future the distinction between new growths and infectious granulomata might turn out to be less than at present supposed. He observed that where there is leucocytosis the spleen is more frequently enlarged than in those cases in which this condition is absent, though, on the other hand, a temporary and variable leucocytosis might occur apart from splenic enlargement. He related a case diagnosed by microscopic examination as spindle-celled sarcoma which had cleared up under arsenic, and he was not therefore in agreement with Mr. Spencer, who concluded that if improvement took place under the use of this drug the disease must be lymphadenoma.

Dr. H. SNOW strongly insisted on the importance of differentiating cancer of the lymphoid tissues from true lymphadenoma or Hodgkin's disease. He recognised three main forms of lymph-gland enlargement, differing from one another widely in microscopic appearance and also clinically. 1. Simple lymphoma. 2. Hodgkin's disease, an obscure general enlargement of glands throughout the body, pyrexial in character, and associated often with pregnancy or exposure to cold or wet, microscopically showing a cirrhosis of the gland, the cell elements being eventually crushed out by redundant fibrous tissue. 3. Lympho-sarcoma or lympho-carcinoma, a true cancer, always primarily local, following injury generally and showing all the features of cancer elsewhere—e.g., progressive cell proliferation, erosion of all adjacent tissues, and progressive tendency to death. He alluded to the marrow as an important adenoid tissue, and thought that implication of this might explain multiple hæmorrhages.

Dr. CLAUDE WILSON made some remarks bearing on the tendency exhibited by speakers to group together, rather than to differentiate, the different diseases under consideration. He mentioned a family in which the grandmother, her two children and two grandchildren all suffered from splenic anæmia, but in which there was no leucocytosis.

Mr. SHATTOCK distinguished between lymphatic growths and tuberculous growths; in the former the tissue was a true lymphatic tissue, whereas in the latter the granuloma consisted of granulatory tissue. He said that it was true that in lymphadenoma the new growth was normal in structure, but he maintained that that also was the case in carcinoma, in so far as it was a reproduction of normal structure, and yet it was malignant.

Dr. WILKS referred to the teaching on the subject in days gone by and asked whether in lymphadenoma the process is not infective in its later stages.

Mr. SPENCER, in reply, said he would like to keep the term lymphoma for affections of the lymphatics and lymphadenoma for those of the glands. He thought that the intervention of a micro-organism was not absolutely necessary for the production of a new growth. Leucocythæmia he regarded as a symptom rather than a disease, and he advised caution in concluding the presence of lymphadenoid growths in the liver and kidneys from the naked-eye changes, as old hæmorrhages bear a close resemblance to them. He argued that the readiness with which lymphadenomatous growths shell out was a means of differentiating them from lympho-sarcoma.

Dr. AULD then read his paper on Hæmatogenous Jaundice, which had been postponed from the previous day, and Dr. HUNTER contributed a few remarks thereon.

Professor BABES (Bucharest) read a paper in French on the Morphology of Pathogenic Bacteria.

Dr. HEWLETT gave a demonstration of the Diazo Reaction in the Urine of Typhoid Fever. The point which he brought forward was that morphine gave the same reaction with Ehrlich's test, even in such dilute solutions as 1 in 5000. He laid stress on the colouring of the froth in the test tube in typhoid fever and with the morphine, which could not be obtained in the urine of patients suffering from tuberculosis and other febrile diseases, though the dark colour in the fluid was obtained with the test. He had tried to obtain a reaction with various other substances besides morphine, amongst which was a fine culture of the bacillus typhosus, but he had not succeeded. In cases of typhoid fever he thought the reaction could be obtained as early as the sixth day, but he did not regard it as an absolutely infallible test. He thought that its absence in a febrile disease (proving the absence of typhoid fever) was of more clinical value than its presence.

Dr. ST. CLAIR THOMSON, in conjunction with Dr. HEWLETT, read a paper on the Fate of Micro-organisms in Inspired Air. From the results of their experiments they were of opinion that in quiet respiration micro-organisms were for the most part arrested by the vibrissæ at the entrance to the nasal passages, and that the mucous membrane of the nose was aseptic.

Dr. SURVEYOR described an experiment which he had made to show that the intestinal gases were void of micro-organisms.

Dr. HEWLETT replied.

The following communications were also made to the Section:—

On Psorospermiasis, by Dr. I. O. W. BARRET and Dr. N. F. SURVEYOR.

The Growth of the Cholera Vibrio in Sunlight, by Dr. F. F. WESTBROOK.

Dr. F. R. WALTERS then read the history and symptoms of a case of Pulmonary Hypertrophic Osteoarthropathy. The patient was shown to the members. Dr. Walters expressed his opinion that the disease was different from acromegaly, and that it was probably due to action on the tissues of the toxines produced by micro-organisms.

On the motion of Dr. F. R. Walters a vote of thanks to Dr. Wilks for presiding was carried by acclamation, and this terminated the proceedings of the Section.

OTOLOGY.

WEDNESDAY, JULY 31st.

Objective Tinnitus.

Sir WILLIAM DALBY, after his preliminary address, which was published in THE LANCET of Aug. 31, showed a case of Objective Tinnitus in a young woman. The noise had existed eighteen months and it did not alter with position. The sound was distinctly audible on approaching the ear to that of the patient, and was of a creaking character synchronous with the pulse. No satisfactory explanation of its occurrence was elicited in the course of the discussion.

Nerve Deafness.

A discussion on the various forms of Nerve Deafness was opened by Dr. DUNDAS GRANT. These might be classified as follows:—I. Diseases of the labyrinth—(1) the labyrinth alone, due to (*a*) circulatory disturances; (*b*) infectious diseases, syphilis, mumps, &c.; (*c*) rheumatism; (*d*) traumatism; (*e*) professional—i.e., the action of sound; (*f*) toxic labyrinthine disease; (*g*) senile changes; (*h*) new growths; (2) labyrinthine disease secondary to middle-ear inflammations—(*a*) chronic catarrhal, including typical Ménière's disease; (*b*) suppurative; (*c*) middle-ear inflammation following general infectious diseases—e., diphtheria, scarlet fever, &c. II. Diseases of the auditory nerve and

Digitized by Google

cerebral auditory centres—(1) neuro-labyrinthitis following supurative meningitis and cerebro-spinal meningitis; (2) cerebral syphilis; (3) intracranial and auditory nerve neoplasms; (4) lesions of the cerebral auditory centres; (5) tabes; (6) hysteria; (7) reflexes; (8) diplacusis; (9) colour-hearing. As regards treatment in the first, or labyrinthine, division, depletion was first to be thought of in circulatory disturbances with a full habit; puncturing of the inferior turbinal was a good mode of procuring the desired effect. Syphilitic cases derived benefit from profuse sweating as obtained by a Turkish bath. This accounted no doubt for the benefit sometimes obtained from pilocarpine injections, which, to be successful, must be employed before the effusion, either mucous, serous, or purulent, has become organised, and should therefore always be tried in the first instance. The remedy was not unattended with risk. It was indicated in symptoms of labyrinthine effusions and hæmorrhage, contraindicated in anæmia. There was a good probability of recovery in syphilitic cases if used at once; it should be laid aside if no effect was observable in a fortnight. All cures reported have occurred in the early stages. The deafness of hereditary syphilis was always rebellious. Hill, McBride, Gradenigo, and others have reported cures, but Dr. Grant had not met with an instance. Pilocarpine should be tried in labyrinthitis following mumps and also in leukæmia and infectious diseases. A case of almost complete recovery in labyrinthitis of scarlet fever was reported in vol. iv. of the *Archives of Otology*. The remedy should be avoided and substituted by galvanism in professional deafness. In labyrinthine disturbance and its sudden loud noises, Delstanche's rarefacteur had been known to produce immediate improvement, by restoring to a normal condition the undrawn tympanic structures and stapes. Pilocarpine is also contra-indicated in toxic deafness, new growths, and inflammation of the auditory nerve due to meningitis. Counter-irritants were indicated in the latter instance, with rest, particularly in leukæmia. To obtain functional rest from noise, the ears should be stopped with cotton wool and the head wrapped up. Cerumen is partially protective in such cases, and it became a question as to the advisability of removing cerumen in the case of boiler-makers and others subjected to loud noises. Sedatives were indicated in mental disturbance, and bromides might be used freely unless the anæmic element was present. The galvanic current was also serviceable in tinnitus. The positive pole should be applied to the back of the neck and the negative to the tragus or mastoid. Four to eight milliampères were to be employed, especially in complicated labyrinthitis following exposure to noise, but the remedy must be employed with discretion. Strychnine was useful, especially in women who were overworked and underfed. Quinine was serviceable in counteracting giddiness and vertigo rather than deafness. Depressants such as colchicum should be given in gouty subjects. The case was mentioned of a lady who suffered from disharmonic diplacusis. She had diplacusis for high-pitched tones. Her Galton was 4·7 on the left side, 2·6 on the right. Under colchicum and the iodide her hearing distance improved, and the diplacusis vanished. Hypnotic suggestion was a remedy of some promise in hysteria. The hysterical deafness was a condition of auto-hypnotism. A related form was common in young girls with amenorrhœa. Dr. Grant, after mentioning the acoustic exercises of Urbantschitsch, and the value as a last resource of lip-reading for deafness, concluded by insisting upon (1) the necessity for a careful diagnosis in nerve deafness; (2) upon the importance of pilocarpine as a remedy in selected cases; (3) recognition of the many-sided character of nerve deafness; (4) recognition of changes in the labyrinth due to senility; (5) recognition of the frequency of chronic aural catarrh as a cause of Ménière's disease; (6) the influence of exposure to noise, and the importance of protection from them.

Dr. MACNAUGHTON JONES enlarged upon the difficulty of isolation of diseases of the auditory nerve, and alluded to fifty cases of absolute deafness which he had published. He considered treatment extremely unsatisfactory, but thought some good was obtained by treatment of so much of the deafness as might be attributable to disease of the middle ear. He thought prophylaxis of great importance, and advised careful watching of children with adenoids. He always insisted that children of deaf parents incurred great risk by residing in malarial districts and further remonstrated against operations upon the nose being suggested for the relief of established and incurable deafness.

In the discussion which followed, Dr. BARR sympathised with Dr. Macnaughton Jones in his remarks on implication of the middle ear, the condition of which should be carefully investigated. With reference to the pilocarpine treatment, he had been disappointed with the results. He now thought that when a cure resulted it was due to a mental effect. The patient made an earnest effort to hear better, but when carefully tested the patient's statements were not borne out. A woman who had sclerosis of the middle ear, with a bad prognosis, underwent the treatment for several weeks in the hands of another practitioner, and at the end expressed herself much better, but he did not discover the slightest improvement, in fact her H.D. for the watch was rather worse. He had used pilocarpine in cases of recent effusion into the labyrinthine spaces when vertigo, tinnitus, &c., were present, but without any benefit.

Dr. LAW raised a question as to the benefit obtainable for deaf patients suffering from secondary, tertiary, or inherited syphilis by the use of mercury or iodide of potassium. Two cases had been under his care lately. In the first, the symptoms of secondary syphilis were present, including roseola rash, iritis, and mucous patches in the throat. Mercury was used in the form of inunction, with rest in bed. All the symptoms excepting the deafness disappeared. After this from twenty-five to thirty injections of pilocarpine were administered without benefit. Subsequently paraplegia developed, the iodide of potassium was administered again, the paralysis disappeared, but the deafness remained as before. A similar case in the secondary stage was treated with a similar result. He had not met with any better success in treating syphilitic deafness in the tertiary stage or in the hereditary form.

Dr. WOODS (Dublin) had had a similar experience.

Dr. MILLIGAN (Manchester) recommended the treatment of the middle-ear in cases of nerve deafness following middle-ear disease. Some cases of nerve deafness were influenced by mental treatment, there were in some cases tinnitus and a temporary absence of bone conduction, requiring change of air, rest, and tonics. He had been most disappointed in the results obtained from pilocarpine in both syphilitic and non-syphilitic cases. He had not found benefit in recent effusions into the labyrinth either. He instanced this fact by a case of a gentleman who was a free liver and a great smoker and who awoke one morning quite deaf. There were all the symptoms of effusion into the internal ear. Pilocarpine injections were given for six weeks without any benefit. He thought that in secondary changes of the auditory nerve, the patient was much better left alone.

Mr. E. H. BENNETT (Leicester) reported three cases of slight improvement. He had lately treated a child which had been for some time under care for keratitis, then deafness came on. He tried pilocarpine and also employed Politzerisation. In a fortnight a slight improvement was noticeable, and then after twenty injections altogether, the parents reported that the child heard as well as ever, but, of course, he was not in a position to state that the result was altogether attributable to the pilocarpine treatment.

Dr. WARDEN (Birmingham) began the treatment of syphilitic cases with the perchloride of mercury, followed by tonics, such as strychnine and hydrobromic acid, and quinine, followed by galvanism. Pilocarpine had made no definite impression on his cases. He agreed with Dr. Macnaughton Jones that large doses of quinine had caused persistent deafness.

Mr. G. P. FIELD repeated his experiences. He thought the treatment of nerve deafness was not satisfactory, but he was satisfied with the good results that might be obtained from pilocarpine if the cases were correctly chosen. He had had a good many successful cases.

The PRESIDENT regretted that Mr. Field could not give scientific details of his successful cases, and summed up the views that had been expressed by the previous speakers. He said with referenee to quinine that the results of administering it were very different in deaf patients from that in those who were well. Healthy people regained their hearing after taking the drug, but deaf people recovered with an increased amount of deafness. Knapp had stated that quinine had been pushed till people were absolutely blind, but they recovered their sight when the drug was stopped. With regard to syphilis, the rule was that in the early stages the nervous loss of the hearing is recovered during the ordinary treatment—i.e., administration of iodide &c.—hence it became a question whether we should pursue

Digitized by Google

any treatment directed to the hearing apparatus unless the middle ear is involved.

Dr. DUNDAS GRANT, in replying, remarked that middle ear complications were not sufficiently treated when occurring with nerve deafness and syphilitic labyrinthitis; sometimes these complications formed an essential part of the case. He thought that the cases of secondary syphilitic deafness that had been brought forward were so bad that a good result from treatment could hardly be expected. Galvanism was most applicable to the class of cases he had termed professional, and to functional cases, as hysteria. With reference to etiology, there was often a multiplicity of causes in operation, as instanced by the case of a gentleman who lost the hearing of one ear and one testicle by metastasis from mumps. He had taken large doses of quinine; last of all he had had syphilis. Galton's whistle was very useful in the diagnosis of nerve deafness. The lowest turn of the cochlea was for the detection of very high tones, and in nerve deafness this function was lost. The capacity for hearing the tones of the middle range was wanting in disease of the intra-cranial part of the auditory nerve. It was difficult to know what attitude to take with reference to the cases of published cures.

Dr. MACNAUGHTON JONES replied by referring first to the pilocarpine treatment, and reviewed the whole history of its introduction. He thought it should be limited to such cases as apoplectiform vertigo, recent syphilis, leukæmia, high tension in the endolymph and perilymph and the like. In old-standing cases of syphilis there was no prospect of any benefit from any measures employed, but in the first stage a combination of iodide of potassium and the ordinary specific remedies with pilocarpine injections constituted a valuable form of treatment. If galvanism was of any use, it was more in the diagnosis than treatment of nerve deafness.

Tuberculous Disease of the Middle Ear and its Adnexa.

Dr. W. MILLIGAN read a paper upon this subject. He remarked that tubercle more often attacked the middle ear than some writers had believed. Painless perforation of the membrane, especially when complicated with facial paralysis, was usually an indication of tuberculous mischief. He had operated upon ten cases of mastoid suppuration in children, and had inoculated guinea-pigs with scrapings from the diseased bone. In eight out of the ten cases tuberculous infection followed, and upon dissection the abdominal and pelvic glands were found to show distinct evidence of tuberculous infiltration. The dissected guinea-pigs were exhibited before the section with drawings, microscopic sections, &c.

The PRESIDENT thanked Dr. Milligan for his original paper, which was deserving of the highest praise. He referred to the painless inflammations that were met with in the tympanum of phthisical and diabetic patients. As regards mastoid operations in children, these often required to be repeated, owing no doubt to the presence of tuberculous foci in the cells, and he related cases illustrating this fact from his own practice.

The Treatment of Intractable Suppurations of the Middle Ear by Operation through the Mastoid.

Dr. BARR gave an account of eight cases of suppurative disease of the middle ear occurring between the age of sixteen and thirty-two years. Four had been operated upon by himself and four by Macewen. In all the cases the purulent mischief had been of long duration—namely, from fourteen to twenty-six years. Careful treatment had been carried out in each case, and the attic, which was involved in the suppurative process in all of them, had been thoroughly syringed out, but no effect had been obtained. The instrument employed was the globular dental burr followed by the gouge, supplied to him by Macewen; the clean surface left by the burr was of great advantage in estimating the depth and direction of the opening. The burr must be hard and sharp, and should be removed every few seconds for cleaning. The burrs of British make were useless. The time from the operation to the total cessation of discharge was from two to eighteen months.

Attic Disease treated by modified Stacke's Operation.

Dr. BRONNER read notes on five cases of attic disease treated by modified Stacke's operation. All previous treatment had failed. The attic alone was opened up. He did not act through the whole meatus, but made his incision in such a direction that allowed of his pulling the ear forwards and downwards. He prolonged his incison forwards. He did not like burrs, but from what the last speaker had said he had no doubt the fault had lain with the burr.

Dr. LAW in the discussion inquired as to Dr. Bronner's results with reference to the hearing power after operations upon the attic.

Dr. MILLIGAN raised the question as to the advisability of retaining a permanent mastoid fistula. He thought it was better to leave a mastoid fistula, and to ascertain this point he had treated one-half of a series one way and another half the other. Another point was the origin of the disease of the attic; he thought it was probably a suppurative condition arising in the antrum, the pus eventually pointing through Schrapnell's membrane. If this were the case we should expose the antrum and remove the disease. The intratympanic syringe was very useful in attic disease, and this, with excision of the ossicles, was often enough to effect a cure. He asked the authors of the preceding papers how long they generally had to continue the subsequent treatment. He rarely got his wounds dry after mastoid operations under a year.

Dr. WOODS asked if previously to the operations boric acid in spirit had had a fair trial.

Dr. URBAN PRITCHARD spoke with reference to instruments. He had always found a great advantage in using the sharp spoon in preference to the burr. In cases where the bone was sclerosed throughout he has had to chisel before reaching the disease. In these it would take much less time to use the burr. He preferred the burr made by Hallam. The malleus should be removed as a preliminary so as to be able to obtain a free drainage through the ear, and in that way to avoid performing Stacke's operation or having recourse to the removal of more bone. He recalled one case under his care at King's College Hospital, in which there was no rise of temperature, and he hesitated to operate, but there was a dirty discharge, and this was a symptom he disliked very much in a man of middle age. He operated, and found a quantity of diseased bone in the mastoid. The wound healed in six weeks.

Dr. BARR, in his reply, stated that the best burrs were to be had from White of Philadelphia; English burrs rode over hard bone, and did not cut out the eburnated bone. As to the class of case operated upon, they were limited carefully to old suppurations that had gone on for years, in which all other methods (including extraction of the malleus in three of them) had failed, and that in the hands of specialists. In regard to the subsequent treatment, three had practically ceased discharging in three months and the dry treatment adopted. Other cases healed much more slowly. Syringing had been diligently practised backwards and forwards, but the treatment went on for eighteen months, during which he had rung the changes on the dry and wet methods. He soon hoped to get quicker results. The operation was still in its infancy, but he hoped it would soon be possible to cure every form of middle-ear mischief.

Dr. BRONNER stated, in reply, that there was in his cases an improvement rather than the reverse in the hearing power.

Dr. LAW showed a series of forty anatomical specimens sent from Professor Politzer.

THURSDAY, AUG. 1ST.

Discussion on Cerebral Complications in Relation to Middle-ear Disease.

Dr. MACEWEN, in opening the discussion, touched upon three points only, and wished the remainder of his paper to be taken as read. The first point was intracranial abscess, the second tubercle of the middle ear, and the third bacteria and prophylaxis: 1. Regarding the localisation of abscess, it was a fallacy to suppose that bone-conduction was present in cerebral abscess and absent in cerebellar disease. It was also a mistake to assume that bacteria reached the brain through the middle ear. Cerebellar abscess arose from disease of the sigmoid sinus, not from that of the internal ear. If the seventh and eighth nerves were intact and the aural mechanism in good order, the auditory nerve would transmit vibrations in spite of the abscess. A case of fatal leptomeningitis with post-mortem report was cited in support of these statements. 2. Tubercle of the middle ear had not received the attention it deserved. It spread slowly and with little pain or no discharge, and sometimes reached an advanced stage without perforation. Tuberculous products formed excellent culture media for pyogenic bacteria; the latter easily found their way into the softened bones. Tubercle bacilli also invaded the blood-stream by finding their way into the sigmoid sinus. In all such cases the mastoid must be freely opened and

Digitized by Google

the tuberculous disease eradicated. The middle ear also formed an excellent incubator; the organisms were afforded all they required in the way of thermic conditions; also food and darkness, and injections practically did them more good than harm. 3. With reference to prophylaxis, Dr. Macewen uttered a caution against conveying disease from ear to ear by means of instruments not properly disinfected. The aurist must be prepared to do more than treat the disorders of hearing; he must be a bacteriologist as well, and his operations are all of them of the nature of bacteriological experiments. In conclusion: (1) the spreading of infection from the middle ear was preventable; (2) when infection was once established we must ensure its eradication.

Dr. LUC (Paris) described a case that had occurred in his practice which was of an insidious character. The patient complained of pain in the occipital region; there had been protracted suppuration from the middle ear and the latter was washed out with a Hartmann's cannula, masses of cholesteatomatous material being removed. After this, Zaufal's operation was performed on the mastoid, the bone being found much diseased; the patient subsequently died, and at the post mortem an abscess was found in the cerebellum.

Mr. MARMADUKE SHEILD regretted that Dr. Macewen had confined his remarks to tuberculous disease. He did not think tubercle of the middle ear was so common as was generally supposed. Naked-eye appearances were fallacious, and the only certain test was inoculation and bacteriological examination. With reference to the disinfection of instruments, he thought much depended upon whether the surgeon made a scratch on the granulation surfaces, for the latter are protective against organisms—i.e., they hinder access to the meninges. He insisted on the importance of removing the infectious foci from the bone when operating, as the least trace left behind acted as a fresh focus for disease. When the latter spread to the base of the petrous bone it was difficult to reach it. He preferred to use a mallet and gouge, and inquired whether Dr. Macewen found it possible to remove all the carious foci by his methods. Regarding the surgical treatment of suppurative meningitis in which a general purulent meningitis extended over the base of the brain, he had not so far succeeded in treating these cases, and he inquired how Dr. Macewen dealt with them.

Dr. MILLIGAN remarked upon a fatal case of cerebellar abscess, in which bone-conduction was good. With reference to tubercle there was no very obvious clinical symptom, but often absence of high temperature, pain, and discharge. The disease was not a simple inflammatory one, therefore it was of greater importance to diagnose it. Inoculation experiments afforded the only means. It was extremely difficult to find tubercle bacilli in the discharge. He narrated the case of a small child in whom he had removed all visible disease, and death ensued from tuberculous meningitis. He could not say that the latter was directly traceable to the middle ear. In a second case death followed from diarrhœa; it was very difficult to remove every trace of disease.

Dr. MCBRIDE referred to the tendency to recurrence of the disease after an apparent cure had been effected. He did not think we were justified in promising a certain cure to the patient by operation. As to the suggestion he had thrown out in a former paper upon the question of diagnosis of cerebellar abscess by means of the tuning-fork, he regretted that what was originally a mere suggestion had since been quoted as a fact.

Mr. BALLANCE said not only did we get cranial complications in tuberculosis of the middle ear, but also serious lesions in other parts. Children suffering from hip and spinal disease often had a history of discharge from the ear, hence the importance of thorough treatment of the ear mischief. Last year he admitted two children to hospital with a discharge from the ear containing tubercle bacilli. There was a good deal of febrile disturbance, but no external sign of mastoid disease. There was at first some relief from the fever after the operation, then the temperature rose again. Eventually both these children died. In the lungs there was abundant post-mortem evidence of tuberculous disease. From these cases he inferred either that the operation was not performed soon enough, or else that the fact remains that we cannot hope for the same success in treating these cases as we meet in other diseases. Referring to what Dr. McBride had stated concerning the tuning-fork test, he had never himself regarded the test as diagnostic, but he should think there was some additional argument towards a diagnosis if no bone conduction was present on one side. Recent researches upon the effects of removing one half of the cerebellum had taught us what signs to look for. All the symptoms were present in the last case in which he operated, including headache, vertigo, vomiting, optic neuritis, nystagmus, deviation of the eye to the opposite side, and paresis of the same side, exaggerated knee jerk and all pathognomonic symptoms. He inquired what Dr. Macewen had to say upon operating on the cavernous sinus. A distinguished Parisian surgeon gave it as his opinion that we could not operate. He thought, however, we ought to be able to operate with some success. He would open the skull and dura mater on the affected side, lift up the temporo-sphenoidal lobe, divide the tentorium, and then make an incision down to the cavernous sinus, and insert a drainage-tube. Referring to the class of case mentioned by Dr. Luc, he recalled that of a child on whom he operated for cholesteatoma which had formed a huge cavity. The child did well for ten days and then died. The pillow was soaked with blood, and death ensued from erosion into the lateral sinus. He (Mr. Ballance) inquired where Dr. Macewen obtained the burrs he employed; he inferred that they were reserved for cases of sclerosed bone. He himself used a broad gouge with a cutting edge at right angles to the handle, three-eighths of an inch broad for the first part of the operation. He thought there was a difficulty in obtaining a permanent cure in Stacke's operation. He did not think Schwarze's was suited for chronic cases. We ought in operating to throw all the cavities into one, so as to have only one to dress. When discharge continued it was because the drainage through the mastoid had not been allowed to continue long enough. A residual abscess remained behind, and more bone must be removed.

Dr. BARR alluded to the danger of removing granulation tissue or polypi from the middle ear without careful antiseptic precautions. He now always subjected the ear to careful antiseptic cleansing for a week or two before removing the granulations, though he knew it was not possible to obtain absolute asepsis. With regard to the tuning-fork he always found that bone-conduction was intensified in the presence of purulent mischief.

Dr. URBAN PRITCHARD recommended avoidance of any treatment of the ear which was not antiseptic, such as syringing with plain water. His plan in a case of small granulations in the middle ear was to syringe with a 1 in 40 solution of carbolic acid several times. Probes were dipped in 10 per cent. carbolic acid in spirit. After scraping out the diseased tissue he dressed the part like a wound with biyanide gauze. On removing the latter he did not syringe, but applied fresh gauze, and on the fourth day he found that small perforations had healed up, the surface being healthy, without a spot of discharge, and there was no trace of infection backwards. He addressed a word of warning to the surgeon: the latter is very apt to try to localise a cranial abscess and operate over that spot, and perhaps successfully, but sometimes he forgets that the mastoid has been the seat of the disease, and he fails to open the antrum and clear out that cavity as well. If we are unable to localise an abscess at first, we should clear out the middle ear by opening the mastoids and antrum, clearing them out, and going backwards to the cranial cavity, taking the lateral sinus as a guide, operating upwards for the cerebrum and below for the cerebellum, and entering the probe carefully in these parts to detect any abscess that may be present.

The PRESIDENT alluded to a paper he had read before the Clinical Society some time ago in which he divided the cases of ear disease that terminate fatally into two classes, which still remained in force. He narrated a case in which he had removed nearly the whole of the temporal bone in a child two years old for disease. He discussed the indications for employing the defensive operations, which were briefly: (1) continuous head pains and giddiness, also for the cure of a hyper- or exostosis; (2) when there was inflammation in the ear with discharge and profuse suppuration, continuing from eight to fourteen days, the patient dying from septicæmia or meningitis, and the discharge being so profuse as to absolutely pour out. In such cases the drainage between the middle ear and the mastoid should be made complete; (3) the presence of epileptic seizures. All such cases should be operated upon.

Dr. ROBERTSON touched upon the after-treatment of mastoid antrum operations. He considered the most effective remedy was the prolonged drainage of the antrum, and he employed a lead stilette for the purpose. Complete cessation of the discharge followed. He deprecated too extensive use of the syringe.

Dr. DUNDAS GRANT had tried the dental burr but gave it

Digitized by Google

up again for the small gouge, owing, he thought, to the inferior quality of the steel. He mentioned a case in his own practice which was similar to that described by Dr. Luc. He extolled the local employment of alcohol in suppurative disease of the ear, it being most potent against sepsis and moisture.

Dr. WOODS showed the brain of a case under his care in which "the operation was perfectly successful but the patient died." The patient had cerebellar abscess, and sank after the operation from no apparent cause. He also described a second case (of leptomeningitis) terminating fatally.

Dr. BARR demonstrated a specimen illustrating the effect of the burr upon a sclerosed mastoid.

Dr. MACEWEN, in reply, stated that he hoped those present had not what he called a statistical conscience, those surgeons who had a statistical conscience were apt to let people die for fear of spoiling their statistics. Sometimes the most hopeless cases got well, in one instance that occurred in his practice recently he thought the patient was dead, he was so absolutely moribund. It was a case of cranial abscess, but the operation was successful, and the patient was now alive and well. He then discussed the diagnosis of cerebellar abscess, and explained why no reliance could be placed upon any one set of symptoms, there was considerable variation in the effect of pressure on the medulla by the abscess, dependent on the fact of its being exerted on both sides or on one only. He agreed with Dr. Milligan's method of experimental inoculation; there was always a probability of tuberculous disease being present in suppurating bone. It was the duty of the aurist to prevent pyogenic infection. Could one prevent general tuberculous infection? This was possible if the disease was limited to the mastoid, and all foci here must be removed. When the disease had spread to the petrous bone it was difficult to eradicate it, but the diseased cavities must be opened up and the walls papered with healthy skin to allow free exit for the discharge. He preferred using burrs to chisel and mallet on account of the impact of the latter, which was thus avoided. He held the handle of the burr like a pen and drilled away the offending parts with the greatest ease; the sinus was easily seen through a thin film of bone and avoided. English burrs were of no use, and he employed those of the American Dental Company.

FRIDAY, AUG. 2ND.

A New Form of Rotatory Vertigo.

Professor GUYE described a case of Ménière's disease in which the rotatory sensations of the patient were of a character hitherto undescribed. He had seen similar cases. The patient was a man aged forty-seven who had had influenza four years ago, but had since been in good health. For two months he had tinnitus in his left ear, and then suddenly (last year) an attack of vertigo. He fell down and vomited. These seizures had recurred at intervals and had not yet disappeared. As regards hearing, he heard the ticking of a watch two inches from the right ear and not at all with the left. His was a typical case of Ménière's disease, and he had shown symptoms of labyrinthine disease. As regards the vertigo, he first saw objects turning round before him in the direction of the hands of a clock, then everything seemed to be turning to the right, and vomiting ensued with giddiness, which obliged him to lie down. Professor Guye then pointed out the distinction between this kind of vertigo and the better known form in which the rotatory sensations are in the vertical axis towards the side of the affected ear. When these sensations are slight there is a tendency on the part of the patient to turn involuntarily in the same direction as the sensation. When the rotatory sensation is strong and sudden it produces a reflex unconscious movement in the opposite direction. These rotatory sensations round a vertical axis might possibly be accounted for by supposing the existence of some irritation of the ampullæ of the horizontal semicircular canals. Other forms of rotation were described. Professor Guye sought to explain these phenomena by reference to the anatomical position of the superior and posterior canals. A slight rotatory sensation in the superior canal would give rise to a feeling of falling forwards or backwards, but around an axis which, instead of being transverse, is inclined to the right or left, according to the side affected. An affection of the posterior canal would give rise to a sensation of objects rotating in front of the patient like the hands of a clock the disc of which is not in front but to the right or left of the patient. More accurate observation on the part of aural surgeons and comparison of clinical with post-mortem observations were required.

Objective Tinnitus.

Mr. CRESSWELL BABER showed a patient, a young woman suffering from Objective Tinnitus, but differing in many respects from Sir William Dalby's case. The sound heard was a soft blowing souffle, very distinctly audible by means of an auscultation tube. It was synchronous with the pulse.

Turbinotomy.

Mr. T. CARMALT JONES read a paper on Turbinotomy in cases of Deafness and Tinnitus Aurium. Removal of hypertrophied inferior turbinals and moriform growths should be practised in cases of deafness and tinnitus where the auditory nerve was in a healthy condition. The naso-pharynx was the cause of much secondary ear trouble. He had operated in upwards of 500 cases. The pain after the operation varied, as did the amount of bleeding. The best anæsthetic was nitrous oxide gas or the A.C.E. mixture, the latter being preferable for children. Notes were read of twelve cases of deafness or tinnitus in which turbinotomy had been performed. Eleven of these were cases of deafness and tinnitus combined. Relief to both conditions was afforded in eight cases; slight relief to deafness only in one. In two there was no relief at all.

A discussion followed in which Mr. BABER, Dr. BRONNER, Dr. MACNAUGHTON JONES, Dr. PRITCHARD, and others took part.

Treatment of Nerve Deafness.

Dr. MACNAUGHTON JONES read a paper on: 1. Some Otological Considerations of the Treatment of Nerve Deafness, based upon a case of Ménière's disease. There had been absolute deafness in one ear for many years. The sound ear was subsequently attacked suddenly. Guy's symptom of reeling towards the affected side was present. Careful study of the cause of aural vertigo was important as possibly leading to a diagnosis. The middle-ear element and all other sources of vertigo being carefully excluded, we were in a position to decide upon the apoplectiform character of the case, and might be able to detect unsuspected disease in other organs than the ear. 2. An extreme case of Hyperæsthesia Acoustica. The patient, a woman aged fifty-five, said her hearing was dreadfully acute. She responded perfectly to the usual hearing tests. Music made her giddy; even a clock in the room was unbearable. Some noises sent a sort of shock up her spine. All this came on after a carriage accident and blow on the head. There was now a great improvement, but not a complete relief, after seven years. He thought that in some cases of hypersensitiveness to sound traceable to middle-ear disorders &c. there was an analogy to intolerance of light as occurring in certain retinal lesions, but he did not think there was any ocular condition analogous to such a typical case of acoustic hyperæsthesia as the above.

Mr. LAKE read a paper, illustrated by specimens, to show that the membrana tympani was in direct continuation with the periosteum of the Eustachian tube and external meatus.

Dr. PEGLER showed under the microscope Sections of Turbinate Hypertrophies. Many showed practically no departure from the normal. His main point was that he had not discovered any true hypertrophy of the visceral muscle fibre in the walls of the vascular sinuses. The second set illustrated the structure of so-called moriform hypertrophies, taken from both middle and inferior turbinates and from the wall of the septum, &c. The complete distinction between these growths and true papillomata, with which they were still confounded, was insisted on. He contended that the papilliform hypertrophies were essentially vascular outgrowths which had gradually become the subject of œdematous infiltration. The muscular walls of the sinuses were invaded by the process, so that they became attenuated, and dilatation followed. As to whether true mucoid degeneration was present or not he was extremely doubtful. Most of the septal growths he had examined were of this character, but true papillomata did occur here as well as on the floor of the meatus.

Mr. CRESSWELL BABER exhibited a set of Dummies designed to educate the fingers of students in the Exploration of the Naso-pharynx.

Digitized by Google

Dr. WARD COUSINS drew attention to a further improvement in the Artificial Drumhead introduced by himself some time ago. The demonstration gave rise to a good deal of discussion, in which the PRESIDENT, Dr. PRITCHARD, Professor GUYE, Dr. LAW, and others took part.

Dr. LAW showed a series of Anatomical Preparations kindly lent for exhibition in the Otological Section by Professor POLITZER.

The work of the Section concluded with a vote of thanks to the President and secretaries.

DERMATOLOGY.

THURSDAY, AUG. 1ST.

Diet in the Etiology and Treatment of Diseases of the Skin.

An interesting discussion on this subject was opened by Dr. ALLAN JAMIESON (Edinburgh) and Dr. WALTER G. SMITH (Dublin). The former in his opening remarks directed attention, first, to the articles of food known to influence skin diseases; secondly, to the maladies of the skin which could be produced or modified by diet; and, thirdly, to dietetics as a means of treatment in dermatology. Some articles of food produced their effect at once, as in the example of shell-fish, and these acted probably by toxic conditions of the blood, though there was the remarkable and unexplained factor of idiosyncrasy which came into play. But far more frequently the action of foods was slow and prolonged, and their precise mode of action was even more difficult of explanation. Referring to certain articles of diet, Dr. Jamieson thought that alcohol seemed to produce a too ready penetrability of the skin, as witnessed by the liability to sweating and the clammy fingers of topers. Alcohol was not liable to produce skin diseases, but it certainly aggravated some disorders. Second in importance only to alcohol comes tea, and it has been shown that tea when taken too hot, too strong, and in excess causes cold hands and feet and a shrinkage of the integument, in addition to gastro-intestinal disturbance. Dr. White of Boston has shown that strawberries and other fruits containing acid in abundance are liable to produce eczema. Persistent omission of green vegetables from the dietary causes relaxation of the cutaneous vessels, and in extreme cases scurvy. It had long been known that persons presenting a pallor of the surface and other evidences of malnutrition and deficient food are predisposed to eczema. As regards the diseases of the skin influenced by diet, certain of them could be at once eliminated, such as parasitic diseases, scleroderma and most hereditary disorders, herpes zoster, and some others. But there remained a large number which are undoubtedly so influenced. Eczema could be produced and modified by unsuitable diet, drinking large quantities of cold water, and other articles. Dr. Jamieson mentioned hurrying over breakfast as a predisposing cause of the disease in school children. Psoriasis was aggravated by alcohol, and he had seen this disease invade the surface more rapidly under the administration of this article. The influence of diet on lichen planus had not been fully investigated, but this disease often arose in overfed, obese women. Boils were undoubtedly sometimes due indirectly to diet, although the disease was essentially a local one. A sudden change from a poor to a luxurious diet, or *vice versâ*, was capable of producing the malady. Acne is very often associated with a spare diet, such as that which schoolgirls were encouraged to take. Lupus is often associated with a distaste for fat. The cause of the increase of cancer during the last half century, as shown by Heath's statistics, was ascribed by Yeo to the increased consumption of butcher's meat, but he thought it ought rather to be ascribed to the undoubted increase in the consumption of tea. He thought that the abuse of this article during the period of growth was the cause of the increase of cancer The subject of diet in treatment was a very large one. Very different diets were called for in the various diseases, always allowing for idiosyncrasy. Alcohol and the regulation of animal food-stuffs were the most important. The latter which contained iron were very important for the treatment of the anæmia which often accompanied acne and other skin affections.

Dr. WALTER G. SMITH read a thoughtful and humorous paper, stating at the outset that we have no certain knowledge of the real action of diet on conditions of the skin. It is difficult enough to trace the action of drugs, and still more difficult in the case of foods. The influence of diet in skin diseases was, he believed, much less important than is generally thought, and after all it might be best to adopt the rule that what most people eat agrees with them most, and what a healthy person finds appetising agrees with him best. There are, however, three ways in which food may perhaps influence skin conditions: 1. *By lowering the general nutrition*—e.g., in scorbutic and purpuric conditions, and those due to a parasite which finds in lowered vitality a more suitable condition for growth and multiplication. 2. *Reflex conditions*—e.g., from stomach to skin, as in over-eating or taking unsuitable food. These conditions were brought about either by a vaso-motor or a purely nervous mechanism. Urticaria and nearly all such skin conditions are known by their transitory character. They may be dealt with by a visit to Carlsbad, but may equally well be treated at home by purgatives, a good cook, and regulating the quantity and kind of the diet. 3. *Toxic conditions of the blood*—e.g., the effects of tinned or unwholesome foods, and the hyperæmia of the skin produced by full doses of alcohol. It must not be forgotten that the skin is the avenue for the elimination of certain substances—e.g., copaiba and other oleo-resins, and highly seasoned foods which are liable to produce erythematous rashes. Turning next to the different diseases of the skin, Dr. W. G. Smith thought they might be grouped into three classes: 1. Cutaneous diseases acknowledged to be influenced by diet, such as the erythemata, acne rosacea, and perhaps acne vulgaris. 2. Diseases which might possibly be influenced by diet, such as psoriasis and some cases of eczema, though he had never been able to satisfy himself that eczema was ever affected by diet. 3. Cutaneous diseases, which are certainly not produced or modified by food—e.g., herpes and lichen ruber. The effect of diet on leprosy had never been satisfactorily proved, nor, in his experience, had boils ever arisen or been modified by dietetic conditions. The fact that people now consumed 136 lb. of butcher's meat per head per annum, as compared with 46 lb. formerly, had been advanced as a cause for the increase of certain diseases; but he would point out that men probably consumed three-fourths more meat (and alcohol too) than women, and he would like to ask whether these diseases were three-fourths more common in the former. As regards salt meat, which was held to be so bad for skin diseases, he had given it to his skin patients without harm. Alcohol, undoubtedly, might sometimes increase the itching and congestion of the skin; but in reference to its supposed effect in producing skin diseases he would point out that the Parsees in India were not exempt from such maladies. If the skin disorder were secondary to diabetes, gastric or other derangements these, of course, must be treated; but as long as practitioners differed so widely and so oppositely it was impossible to believe that diet had any important effect on the skin condition itself. By way of summary Dr. W. G. Smith stated his belief—(1) that very few skin diseases were directly produced by food (though diet may aggravate some already in existence); (2) that the diseases so arising are always erythematous and transitory; (3) that diet has no influence on the cure of skin diseases, even of acne; and (4) that the only practical rules necessary are to exercise moderation and temperance in all things, and especially in alcohol, to regulate the bowels, and to cure the anæmia if present.

Dr. RADCLIFFE CROCKER agreed with Dr. W. G. Smith in thinking that the influence of diet had been exaggerated. He thought that salt meat and some other unwholesome articles acted chiefly by producing gastro-intestinal catarrh. The cooking and mode of preparation were even more important than the article. As regards the effect of alcohol, it differed widely in the different forms of alcohol; thus beer and port wine might do harm when well-diluted spirit would do good. Boils sometimes occurred in states of lowered vitality, sometimes in very healthy persons.

Dr. A. J. HARRISON (Clifton) agreed with Dr. Jamieson as regards the effects of acid fruits and the causation of boils; but as regards eczema he mentioned a patient who had been getting worse under a restricted diet, but who became rapidly well with a liberal and varied supply of food.

Dr. THIN adverted to the fact that tea was more largely drunk in China and Japan than in England, yet the inhabitants of those countries were not more troubled with the skin maladies said to be so produced.

Dr. MORGAN DOCKRELL believed emphatically that diet played a most important part in diseases of the skin. Amongst other maladies lupus might be mentioned. This disorder was rare amongst the Jews, and he thought the

Digitized by Google

circumstance might be accounted for by the careful inspection to which the meat was subjected preventing tuberculous meat being eaten.

Dr. MCCALL ANDERSON would not wish to minimise the importance of diet in the causes and treatment of skin diseases, but he rarely gave much heed to the diet of his skin patients. He did not think tea was likely to do much harm if properly prepared, but if taken too hot or too strong it might give rise to trouble, though this would be chiefly of the alimentary tract.

Dr. SAVILL, though agreeing generally with those who held that diet was not of great importance, wished to emphasise the effect of alcohol in skin maladies. He referred to Anstie's experiments on alcohol which showed that this substance produced vaso-motor dilatation of the dermal vessels and lowered oxidation of the tissues generally. In his experience the omission of alcohol from the dietary had frequently led to recovery from skin disorder of very long duration.

Dr. STOPFORD TAYLOR (Liverpool) and Dr. MYRTLE (Harrogate) also took part in the discussion, and Dr. JAMIESON and Dr. W. G. SMITH replied. The former wished to emphasise the fact that it was not diet *per se* which gave rise to boils, but sudden alterations in the dietary and mode of life which predisposed to them. The latter strongly deprecated the use of the word "gouty" applied to skin maladies as unscientific and unmeaning; and, referring to tea, said that after listening to the remarks that had been made about this dangerous article of diet, he could well understand the derivation of the word "gunpowder" as applied to a certain kind of leaf.

Lichen Planus Verrucosus.

Mr. GILBERT SMITH (Birmingham) read a paper on a case of Lichen Planus Verrucosus. A woman aged forty years was admitted to the Birmingham Lock Hospital on Feb. 4th, 1895, with a severe eruption on both legs and a slight eruption on both wrists. The rash had started eight months before as a small hard pimple like a corn, about the size of a pin's head, on the outer side of the right ankle. Other pimples rapidly appeared in the same region, forming a patch its present size—three inches in diameter. Over the front of the same leg other patches formed in the same way, hard papules also appearing between the patches and extending up the thighs. Three months later the left leg became affected in the same way, but to a less extent. On admission the patient was found to be well nourished, but had a greyish-coloured skin and an anxious expression of countenance. The eruption was confined to the legs and arms. Over the front and sides of both legs were a number of dark-brown patches, raised somewhat abruptly, their centres being much darker than their periphery. The patches varied in size from a pea to about two inches in diameter. The centres of these patches examined with a strong lens had the appearance of a group of closely packed horny plugs. Between these patches and extending more or less over the whole of both legs for some distance up the thighs there were inflamed hair follicles raised and tipped with hard, horny plugs. The eruption on the extensor surfaces of both forearms and wrists was slight, and composed of the typical angular patches of lichen planus. The patient suffered from severe neuralgic pains and irritation in both legs, especially at night. Severe cramps and sick headaches with vomiting troubled her daily. Her general health had been bad ever since the birth of her last child fourteen years ago. Her confinements had always been difficult. There was a marked history of uterine disease until relieved by an "operation." For eight months before admission she had suffered from severe headaches accompanied by vomiting, and every night she had had severe cramps and twitchings of the muscles of the legs. The case was interesting, first, as showing a probable cause of nerve exhaustion consequent on derangement of the generative system in a nervous temperament; secondly, on account of the extent of the eruption; and thirdly, in showing that the warty patches were derived from conical papules seated at the hair follicles, and not from flat papules. That the process is the same as lichen in planus is shown by the presence of a few typical flat papules in other and more usual positions.

Dr. RADCLIFFE CROCKER remarked that such cases were very interesting, as illustrating the follicular origin of these flat papules, and the patches which are built up by coalescence of papules around the sebaceous orifice. These cases also reveal the anatomical relationship of lichen planus—where the papules are usually flat, but may, as we now see, be acuminate—and pityriasis rubra pilaris, where the papules are usually conical, but may be flat.

Dr. NORMAN WALKER (Edinburgh) objected to the use of the word "verrucosus." Looking at the photographs, the papules were not excrescent and warty, but flat. A follicular papule due to hypertrophy of the cuticle should not be called warty, for a wart consisted of dermal overgrowth.

Mr. GILBERT SMITH, in reply, mentioned the extreme rarity of the affection. Out of 22,000 cases he had only seen this one.

The Treatment and Prognosis of Ringworm, based on the Physiology of the Trichophytons.

Dr. LESLIE ROBERTS (Liverpool) read an important communication on the Treatment and Prognosis of Ringworm, based on the Physiology of the Trichophytons. These organisms, he said, always affected the hair; and hair, considered scientifically, was the formed secretion of the cutaneous follicle. Chemically it was as remote from the living substance of the body as it was possible to be. It was unaffected by the soluble ferments, whether acting in an acid or alkaline medium. It was proof against the agents of putrefaction. In the mineral kingdom it was disintegrated and partially dissolved by certain substances whose action was considered by physiologists as analogous to the action of soluble ferments—namely, by strong acids and alkalies. There existed in the vegetable world a class of minute flowerless plants containing a ferment by whose agency hair could be more completely dissolved than by the strongest acids or alkalies. These minute plants were the keratolytic fungi.[1] Chemically speaking, ringworm consisted in the disintegration of the complex carbon-nitrogen compound, keratin, into a simple carbon compound and a nitrogen compound, which were assimilated by the fungus. It followed from these facts that when once the fungus had entered into the interior of the follicle it was master of the situation, since it possessed a power, which we did not, of digesting keratogenous tissues without employing the use of caustic agents. We were, therefore, at a complete disadvantage in our efforts to control the fungus. The lesson which we had to learn was that when once the fungus had entered into the interior of the follicle we ceased to have any further direct control over it. Dr. Leslie Roberts then entered upon the inquiry of the ways and means at our disposal for controlling the operations of the fungus. We had it completely in our power to prevent the development of fresh foci and the scattering of the fungus from one part to another, since the fungus always travelled from one follicle to another by the external surface; but when once the fungus had entered into the interior of the follicle we could influence its life only in an indirect way. This indirect therapeutic influence consisted in our power to artificially provoke proliferation of the living cells of the follicle and to excite the subjacent bloodvessels. After referring to some practical points in the anatomy of the hair follicle, Dr. Leslie Roberts entered upon the relationship of the fungus to the living hair-forming cells. He said its action was to inhibit the normal proliferation of the cells, and sometimes this inhibition was absolute for a time, as in tinea decalvans. It was just on these cells that our therapeutic influence could be brought to bear by means of irritants deposited upon the surface of the skin over the affected follicles. Under normal excitement physiological proliferation resulted, of course, in the formation of hair and the thin insoluble membrane (inner root sheath) lining the interior of the follicle. If the excitement went beyond physiological bounds proliferation became luxuriation, and pus was the result. The formation of pus commonly a useless product, was of great service in the morbid condition of the follicle now under consideration. The practical difficulty was how to control the suppuration. Pus, which resulted from inflammation of epithelium, was produced without any considerable loss of substance and without ulceration; but loss of substance and ulceration were invariably the result when pus was produced in connective tissue. Regarded in this light the problem of how to treat trichophytosis follicularis (ringworm) could be enunciated as follows: to excite the soft cells of the affected follicles to a physiological proliferation, or to a luxuriation (pus formation) which shall not pass beyond the limits of the epithelium. The remaining portion of the paper enlarged upon this theme and concluded with a summary of the present state of our knowledge of the pathology and therapeutics of the disease.

[1] The experimental proofs are given by Dr. Leslie Roberts in the Journal of Pathology and Bacteriology, vol. iii., July, 1895.

Adenoma Sebaceum.

Mr. WILLIAM ANDERSON narrated a case of Adenoma Sebaceum treated by Excision. The patient was a man aged twenty-seven years, in whom the disease had commenced when he was seven years of age with a few spots on each side of the nose, which grew and multiplied until a great portion of the face was covered. Spots of a different character had appeared on the trunk somewhat later. The family history was negative, and his health had always been good. On admission to hospital he had a large number of pale, brick-red papules varying in size from that of a millet-seed to a pea scattered over the face, but grouped most closely around the naso-labial and labio-mental furrows. Scattered over the trunk, but chiefly collected over the loins and scapulæ, there were a number of mollusca fibrosa, and also some irregular, slightly raised patches, apparently due to the same fibrous growth as the mollusca. There were no subjective symptoms, and the patient was of robust health and good average intelligence. He had never suffered from dyspepsia or any other variety of skin disease. He had been subjected to various kinds of treatment without result. The disease caused much disfigurement, and though it had been stationary during the past year it had shown no tendency to recede. An incision was made along the course of the naso-labial and labio-mental folds and the most conspicuous groups removed. The wound was closed with subcuticular sutures and dressed with iodoform and collodion. Some of the outlying patches were shaved off, and the rest left for a subsequent operation. Some fine linear, hardly noticeable scars resulted, and the loss of redundant tissue improved the contour of the face. Mr. W. Anderson remarked that the case resembled those recorded by others, but it might be noted that the man was of good intelligence and had never suffered from acne or dyspepsia. In the association with mollusca fibrosa it resembled one recorded by Dr. Vidal. The linear scars occupying the position of normal furrows were, he thought, a distinct improvement on the pitted cicatrices which invariably followed the application of galvano-cautery.

Alopecia Areata.

Dr. HENRY WALDO (Clifton) read a paper on Alopecia Areata. He wished to limit his remarks to the circumscribed as distinct from the universally diffused variety, which was generally regarded now as of tropho-neurotic origin. In view of the fact that no one micro-organism had been demonstrated in all or even in most cases of patchy alopecia, he could not subscribe to the parasitic theory of production. Atrophy of the follicle and its contents appeared to be the most constant condition present, and Dr. Waldo believed the cause was often overwork with too little sleep, combined with unsatisfactory hygienic conditions and general malnutrition; worry, anxiety, and nervous shock also played their part in some cases. He had obtained the best results by improving the patient's general condition and by the administration of cod-liver oil and arsenic—two remedies which are also useful in other neuroses—combined with rest and out-door life. Patients often get well without the application of a parasiticide or other local applications, a fact which strengthens the neurotic theory; but moderate stimulation of the more or less anæsthetic surfaces was often advantageous, as, for example, compound tincture of camphor well rubbed in and around the patches. He had not tried oxygen gas, but had used thyroid extract internally with uniformly negative results.

Dermatitis Repens.

Dr. STOWERS exhibited Coloured Drawings of Dermatitis Repens, illustrating a very severe and persistent case in a female. The disease commenced at the age of twenty-seven, forty-four years previously to her death from cancer of the stomach, and continued more or less severely during the whole period. He described in his paper the characteristic features of the ailment, and pointed out the grounds upon which it was accepted that dermatitis repens begins as a peripheral neuritis followed by secondary changes of an inflammatory nature completely destroying the whole structure of the skin. The thumbs of each hand were first involved, but after varying intervals the fingers and toes followed, the nails becoming detached and the matrices destroyed. The history of the case suggested an idiopathic origin, although the few cases previously recorded invariably followed injury to the fingers or hand, from the site of which the morbid process began. The patient was originally in the enjoyment of fairly good health, but occasionally suffered from acute gout, her father having been the subject of gouty trouble from early manhood until the time of his death. Concurrently with the dermatitis the condition known as "glossy" skin appeared and remained throughout. The affection spread towards the trunk, and at one time included the skin of the shoulders, chest, and abdomen in a lesser degree; but eventually this disappeared, leaving the hands and feet only involved. Dr. Stowers considered dermatitis repens to be best described as a spreading dermatitis denuding the epithelium by a slow process of disintegration, accompanied by irregular pustulation, discharging a serous or sero-purulent fluid, and spreading with an undermined and generally well-defined edge. The treatment of the case had proved unsatisfactory, the numerous remedies prescribed alike failing to arrest the disease.

Dr. EDWARD MACKEY (Brighton) read a paper on Cheiropompholyx in association with Eczema; Dr. FRANK H. BARENDT (Liverpool) read the notes of a case of Cheiro-Pompholyx.

The Etiology of Acute Pemphigus.

Mr. GEORGE PERNET read a paper on this subject, founding his remarks upon a fatal case of acute pemphigus which had recently come under his observation,[1] and stating that he had been able to collect four other very similar cases, all like his own, occurring in young journeymen butchers. In three, the disease was fatal in from ten to twenty-eight days. In two cases, one of which recovered, there was a distinct history of a wound, inflicted whilst dressing sheep's heads. He also alluded to two other cases. Adding the whole of the cases together (seven), including his own, no less than six terminated fatally, and in three there was a distinct history of an injury to the hands. In a second series of cases he had collected (eight in number), apart from butchers, but where the nature of the occupation brought the patient in contact with animals or dead portions of animals, the acute bullous eruption was fatal in five (four females, one male). In three of these eight cases there was a distinct history of injury to the hands, and in two others a whitlow of the finger was noticed on admission to hospital. The case of a man who attended horses and milked cows was specially interesting from the fact that the disease followed a wound of the hand and was contracted by inoculation from the teats of a cow. Mr. Pernet then touched upon bullous eruptions found in horses, cattle, &c. With regard to the bacteriology of the case which he had observed, a diplococcus had been found by Dr. W. Bulloch[2] which agreed with the organism first described by Demme, and more recently by Claessen. Mr. Pernet arrived at the following conclusions: (1) there was a group of rare cases of acute bullous eruption, accompanied by severe constitutional symptoms, and generally terminating fatally, which affected butchers; (2) the disease followed a wound of the hands or fingers, and (3) was probably due to a micro-organism; (4) the same etiological factors were probably at work in another group of very similar cases, and affected those who handled animals or dead portions of animals, such as hides, meat, &c. He suggested that in future the following points should be looked for in cases coming under observation: (1) occupation, (butcher, &c); (2) history of a wound; (3) presence, or absence, of a characteristic micro-organism, i.e., Demme's diplococcus; and (4) contact with animals. In conclusion Mr. Pernet insisted on the importance of thoroughly disinfecting, with powerful antiseptics, all wounds of the fingers and whitlows in butchers and those handling meat, &c.

FRIDAY, AUG. 2ND.

This day was entirely set apart for the exhibition of patients. They were so numerous as to block the approach to the room where the meeting was held. Drawings and microscopic preparations were also shown, and there was a large attendance of members.

Exhibition of Cases.

Dr. COLCOTT FOX showed two cases and gave a short description of a Papulo-pustular (acneform) Eruption which he had met with in infants. The children shown, of whose cases the notes were read, were about seven or eight years of age, but it usually appeared in infancy or early childhood. The disease seemed to be a rare one, as he had only seen ten

[1] British Journal of Dermatology, April, 1895.
[2] British Journal of Dermatology, May, 1895.

Digitized by Google

cases. The eruption was an indolent, chronic papulo-pustular (acneform) rash and was disseminated over the body, though chiefly occurring on the extensor surfaces of the limbs, the upper part of the buttocks, and the face. The small papulo-pustules were seated about the hair follicles, being at first more or less acuminate in shape, but in the stages of involution they were flat topped, polished, puckered at the borders, and simulating lichen planus. There was a central plug in the follicle, and this often fell out, leaving a little crater. There was neither itching nor any other subjective symptom, but the disease seemed often to arise in debilitated subjects. The eruption had well-marked physical characters and distribution, all the cases presented precisely similar characters, and the disease might therefore be regarded as a distinct entity. One of the children was said to have had "snuffles," and in another there was a suspicion of syphilis in the mother. In two of the cases scrofulo-tuberculous nodules were present. Dr. Fox said the eruption was not amenable to antisyphilitic remedies, and he had never seen it in undoubted cases of syphilis. It could not be regarded as of syphilitic origin. On the other hand, the subjects of it might be called strumous and were sometimes tuberculous. He ranged the affection alongside a similar eruption termed "acne scrofulosorum," met with in older children and adults who were scrofulo-tuberculous. It was, however, probably not directly due to tuberculosis. It yielded to tonic treatment and cod-liver oil.

Dr. RADCLIFFE CROCKER remarked on the rarity of the affection, though he had met with and recorded cases, and emphasised the distribution of the eruption and its predilection for the face and buttocks as an important diagnostic feature. He had not observed any evidence of contagion. He preferred the name "acne scrofulosorum." It was undoubtedly the same disease which he had described under that name, and it was interesting to find from Dr. Fox's observations that the malady occurred in infancy as well as in childhood and adult life, at which times only he had seen it.

Dr. ALLAN JAMIESON thought that it was the same disorder as that of which he had published two cases in the *British Journal of Dermatology*, and that one of the illustrations in the New Sydenham Society's Atlas figured a similar disease, though it was labeled as a variety of molluscum contagiosum. He agreed that the disease was a distinct one, but preferred the name "acne varioloformis." In cases he had observed the crateriform depressions were well marked, but there was no pitting. In one instance, where two children of the same family were attacked, there was distinct evidence of infection. His patients had got well with boracic baths and salicin ointment. The disease was undoubtedly rare.

Dr. WALLACE BEATTY had seen a case in Dublin.

Dr. MORGAN DOCKRELL thought it a pity to call it acne, as it differed from this disease in its pathology. It seemed to him to be a papular disease of tuberculous origin.

Mr. MALCOLM MORRIS showed four cases: 1. A case of Symmetrical Scleroderma in an elderly woman, ulcerating in places. These ulcers might, he thought, be regarded as of trophic origin. They were, as usual, exceedingly painful. 2. An unusual form of Tuberculosis of the Skin, for which Mr. Morris proposed the name "lupus vulgaris erythematoides," for in some respects it resembled lupus vulgaris and in others lupus erythematoides. It was not symmetrical and did not attack the face as in the latter disease, but copied it in its process of repair. Mr. HUTCHINSON and Dr. MCCALL ANDERSON objected to the use of the term "erythematoides" in such cases, which in their main characters corresponded with lupus vulgaris. 3. Two cases of Leprosy. The first patient exhibited had been born in India and first noticed the disease in 1881, when ulcers began to appear on the fingers. In 1887 he first came under Mr. Morris's care, when there were patches of absolute anæsthesia and great atrophy of the phalanges of the feet and hands and wasting of the muscles, also ulcers due to pressure, a tuberculous appearance of the nose, and the typical drawn-up position of the hand. The second leprosy patient, aged forty-nine, had resided in Australia and India. The disease began in 1886 with patches over the back and elsewhere which were described as "erythema" at a London hospital where he went, and where the anæsthesia and paresis from which he suffered were supposed to be malingering. Nothing more definite appeared till January, 1893, shortly before he came under Mr. Morris's care upon his return to England. At that time he had ringed patches all over the back and chest accompanied by anæsthesia and paresis of the limbs. He was put on chaulmoogra oil and had taken from sixteen to twenty capsules a day of four minims each for a long while, altogether having taken some 10,000 capsules. Consequent on this the lightning pains from which he had suffered had entirely gone, the anæsthesia and ringed patches had disappeared, and the general health was extremely good. Mr. Morris thought the recovery might fairly be attributed to the oil. Mr. Hutchinson considered that residence in England was an important factor in the recovery of these cases, and mentioned a patient resembling this one who had been under his care and who got well while living a healthy life in England without any special treatment.

Dr. RADCLIFFE CROCKER (President) exhibited six patients: 1. Two cases of Morphœa or Circumscribed Scleroderma of the Fifth Nerve. 2. A case of Urticaria Pigmentosa occurring in a patient aged nine; it was an inveterate disease which usually begins in the first year of life, but which in this case began at the age of six. This child also exhibited well-marked urticaria factitia. She had improved under small doses of arsenic long continued. 3. General Scleroderma in the atrophic stage in a man aged thirty-nine who had suffered from the complaint for three years. The skin presented a nævoid condition in parts, and the fingers were drawn up and stiffened. He was recovering now and the sweat function was returning under Turkish baths followed by massage. 4. Psoriasis after treatment by salicylate of soda, 15 grs. three times a day. The treatment had been commenced on May 11th, and there was now great improvement. The patient had formerly been treated by thyroid extract, with only slight improvement, although he had had the great advantage of being in bed as an in-patient. 5. Xeroderma Pigmentosum in a patient aged twenty-one. It had begun as usual in the first year of life, and the brown spots had the usual distribution over the face and bust, and the alæ of the nose were scarred. A brother and a sister were similarly affected, only one out of a family of four escaping. Treatment had been unavailing. 6. General Alopecia of five years' standing in a boy five years old, on whom oxygen gas had been tried for three months with doubtful success.

Mr. GEORGE STOKER brought forward a little girl formerly the subject of Alopecia of about one month's duration, but who now had plenty of long white hair, consequent on treatment by oxygen gas. She had at first taken thyroid extract, one tabloid a day for three weeks, with no effect. She had worn the oxygen cap for two months with this beneficial result. Mr. Stoker thought the cause of failure in Dr. Crocker's case might be non-fitting of the cap. He had been induced to try it in alopecia because he found when treating ulcers that the cutaneous hairs beside the ulcer grew so rapidly. The child's hair had been becoming pigmented.

Dr. COLCOTT FOX exhibited three patients. 1. A case of Mycosis Fungoides in a man aged forty-six. The malady had commenced ten years previously with ill-defined eczematoid patches, which in the course of two years presented the typical appearance now seen—solid infiltrating fungating purple ovate tumours of variable size, ulcerating on the surface and situated chiefly on the arms. A general eczematous eruption was scattered between the tumours. 2. A case of Ulceration over the Manubrium of twelve years' duration, which from its characters Dr. Fox regarded as Rodent Ulcer, though its position was unusual. During the last two years he had met with two instances of this disease on the arm, one on the back, and one on the scrotum. 3. A case which might perhaps be regarded as a kind of Recurrent Summer Urticaria of a most intractable kind, and which had affected a boy aged eleven during the past six years. In winter the eruption was comparatively quiescent, but in summer it presented the appearance of rounded, raised erythematous papules the size of a split pea, sometimes, as on the face, becoming confluent, accompanied by itching and burning sensations. These wheal-like lesions were scattered over the body and limbs. There was a history of vesication, but he (Dr. Fox) had not observed it. He had seen several similar cases, and was doubtful whether the disease was to be regarded as a special variety of chronic urticaria or as a papular, erythematous, mild form of hydroa vacciniforme (Bazin) vel hydroa æstivale.

Dr. JAMES GALLOWAY exhibited a patient, a Polish Jew, suffering from Multiple Pigmented Sarcoma of the Skin which at one time had involved the limb with such large masses that amputation had to be performed. Now most of the pigmented, walnut-like growths had disappeared by natural

Digitized by Google

involution and only scarring was left. The patient had improved while taking arsenic, but the improvement had probably been spontaneous.

Dr. ABRAHAM COHEN also showed a case of supposed Multiple Sarcomatous Dermatosis in a Polish Jew involving the fronts of both legs. Circular, closely clustered, warty papules of a dark-brown colour could be seen spreading over the middle two-fourths of the skin of the front of the leg, being replaced in some of the central parts by whitish scar tissue the result of a cicatricial healing. This disease, Dr. Cohen said, was almost entirely confined to Central and Eastern Europe and did not affect Jews in other parts.

Dr. PYE-SMITH brought two cases to the meeting. 1. A case of Acanthosis Nigricans which presented certain interesting features. The disease had only appeared five or six years before, since which time the skin generally had assumed a deep bronze colour, but especially over the trunk. The characteristic pigmented warts (papillomata) were to be seen forming a patch on the side of the neck and on the abdomen. In youth the patient had had ulcers, probably tuberculous. Soft soap and warm water had much improved the patient's condition, but had not removed the disease. 2. A young, healthy soldier from India, with numerous Cysticerci under the Skin. A number of small globular tumours about the size of small beans, situated just beneath the skin in the subcutaneous areolar tissue, produced the idea that they might be lipomata, but the removal of one of them showed that they were cysts containing the characteristic fluid and hooklets; thirty or forty in number, they were scattered over the entire surface, though mostly on the legs, arms, and face.

Dr. ALFRED EDDOWES exhibited three patients. 1. A case of Eczema Palmare cured by an ointment consisting of acid. salicylic., 2 dr., ung. hydrarg. oleatis, ad 1 oz. The patient was a washerwoman who had been prevented from doing her work by the complaint for two years. She had been under treatment for three months, and was now able to resume her washing and other work. 2. A case of very chronic Eczema in a boy aged eleven. 3. A case of Angiokeratosis on the leg of a female patient aged fifty-four. There had originally existed a number of large varicose veins reaching from a short distance below the knee almost to the ankle. The disease, which consisted of a purple, horny surface, had been sharply defined and entirely confined to the skin over the veins. The affected parts had been treated with creolin as well as iodine, and the limb covered with zinc gelatine and bandages, one of which dressings had remained unchanged for many weeks. As the result of the treatment, and perhaps also of the disease, the varicosity of the veins had completely disappeared, and the leg appeared to be cured, a little redness and superficial scarring only remaining.

Dr. MORGAN DOCKRELL demonstrated two patients. 1. A case of Ichthyosis Hystrix (vel Sebacea) in a girl aged fifteen, who had, as is usual, had the disease since birth. It differed, however, from most cases in that the wart-like excrescences were confined to the face and scalp. Dr. Dockrell thought that it corresponded more or less with the sensory nerve distribution. 2. A case of Adenoma Sebaceum in a boy aged ten who had been affected ever since birth. It was chiefly on the face, being more on the left than the right side. Associated with this were telangiectodes and freckles, and some cicatrices were believed to indicate that some of the growths had undergone spontaneous involution. The disease was associated, as it not infrequently is, with epilepsy, and two attempts to procure specimens for microscopic examination had brought on fits.

Microscopical specimens of a Diplococcus which Mr. GEORGE PERNET had found in a case of Pemphigus were also exhibited.

A large number of drawings of different diseases were also shown, and Dr. F. M. SANDWITH (Cairo) exhibited some interesting photographs and water-colour drawings of patients suffering from Pellagra, a disease due to eating mouldy or diseased maize, which affects the poorer inhabitants of Egypt, who consume this as an article of food. The sketches showed well the pigmented erythematous patches, which appear only on those portions of the body and limbs exposed to the solar rays. The disease is well known in Northern Italy and elsewhere, but this is the first occasion of its having been reported from Egypt. Besides the skin the poison affects also the digestive and cerebro-spinal systems, and many cases of melancholia and dementia in the Italian lunatic asylums are now known to be due to this disease in a chronic form.

THE MUSEUM.

(Continued from p. 444.)

IV.—SANITARY APPLIANCES.

SANITARY appliances were not conspicuous quite by their absence, but rather by their somewhat meagre representation. Possibly this was on account of the pressure upon space, although of course we do not admit the secondary importance of the subject. Sanitation of a strictly medical kind, as that involved in surgical operations, midwifery, the aseptic treatment of wounds, and so forth, could not possibly be omitted in the demonstration of an exhibition of interest to medical men, but we should like to have seen more illustrations of practical sanitation, as, for example, the disinfection of clothing, of rooms, hospital wards, &c. The most important exhibit connected with this subject was undoubtedly that of Messrs. Defries and Son (Houndsditch), who showed the merits and demerits of various filtering media as illustrated in the chemical and bacteriological effect of these upon water. The Pasteur filter, which stands prominently out as having resisted more than any other form of filter the passage of pathogenic organisms through its pores, was submitted to inspection in various patterns severally suitable for table, travelling, service-pipe, cistern, and other purposes, while diagrams were on view showing the application of the Pasteur system of filtration applied on a large scale. Practical disinfection was represented in the ingenious "Equifex Spray Apparatus" for disinfecting rooms where steam is not available or cannot be applied, and in the Equifex saturated steam disinfector for operating theatres. Illustrations were shown also of the Equifex saturated steam disinfector at medium pressure for public disinfection stations, hospitals, &c., and of the Equifex valveless saturated steam disinfector at low pressure for small town stations, hospitals, casual wards, &c.; also of the Equifex boiling-pan for tuberculous sputa, linen, &c., giving a constant temperature of 100° C., and of the Equifex cleansing disinfectors for cattle markets, stables, &c.—all giving evidence of a thorough acquaintance with the developments of modern bacteriological research and of a practical knowledge of the real requirements of present day disinfection. Messrs. Defries and Son also explain the working of a convenient portable air-testing apparatus, designed by Dr. Scarfield, which enables the observer to obtain a fairly approximate estimate of the efficiency of the ventilation of any given space.

In addition to their well-known and comparatively innocuous but powerfully germicidal creolin preparations, the Jeyes' Sanitary Compound Co. (Cannon-street, E.C.) exhibited a sanitary appliance which, though not new on the Continent, is a novel introduction in this country. It consists of an automatic toilet-box for the watercloset containing papers impregnated with Jeyes fluid, which are delivered one at a time by an ingenious folding arrangement through an opening underneath. The method is one we should like to see generally adopted. Cresol is the basis of the powerful antiseptic fluid of Messrs. C. J. Hewlett and Son (Charlotte-street, E.C.), who also supply some excellent antiseptic jellies, containing 1 part per 1000 of corrosive sublimate combined with agreeable substances like thymol, eucalyptus, otto of roses, &c. An emollient antiseptic cream (in collapsable tubes), which is said to give instant relief in the itching of cutaneous diseases, belongs also to the list of useful antiseptic preparations of this firm. The list of Sanitas preparations is now so great as to comprise a complete antiseptic and disinfectant armamentarium. The composition of most of these is based on "Sanitas" (Sanitas Co., Bethnal-green), a deservedly popular, pleasant, and moreover active compound. The pocket sanitas disinfector, consisting of a small glass bulb enclosed in cotton-wool and containing a sanitas compound, is convenient for extempore use. The merits of the various sanitas soaps, exhaling the pleasant fragrance of sanitas and eucalyptol, have already been discussed in our columns.

Sulphur in various convenient forms (candles, cones, &c.) for disinfectant purposes was exhibited by the last-named firm and by Messrs. Macfarlan and Co. (Moor-street, E.C.), and also Messrs. Seabury and Johnson (Snow-hill, E.C.). Sanitary specialities were represented in the excellent display of towels, accouchement sets, sterilised dressings, &c., of Messrs. Southall and Barclay (Birmingham), whose successes in this branch of sanitation are well known; while the exhibit of the Peat Industries Syndicate (Queen

Digitized by Google

Victoria-street, E.C.) contained the peculiar and interesting products of peat fibre, which has proved so valuable as a surgical dressing,[1] and even for the manufacture of hygienic articles of furniture and clothing, as "hygienic socks," mattresses, sanitary covers, blankets, &c. Consistently with their reputation, Messrs. Duncan, Flockhart and Co. (Edinburgh) now produce a good soap superfatted to the extent of 3 per cent. It is prepared from the best materials, and is very agreeably and delicately scented. "Beaumol" soap, as it is called, is also made in the form of carbolic, coal-tar, and terebene soap. Last, but certainly not least, must be mentioned the patent wood-wool preparations (Hartmann) now manufactured solely by the Sanitary Wood-wool Co., Ltd. (Thavies-inn, Holborn-circus, E.C.). Eminently adapted for antiseptic and absorbent purposes in the treatment of wounds and of every kind of discharge, and cleanly to a degree, these preparations, dressings, &c., supply a want that was long unfulfilled.

V.—MINERAL WATERS, BEVERAGES, &C.

The mineral water industry was well represented, and it is a pleasure to record the strict measures and precautions that are now being taken by most respectable mineral water makers to ensure the utmost possible purity of the materials and water used in the production of this important class of beverage. On the stall of the Idris (Camden-town) exhibit, for example, were to be found the appliances necessary for the chemical and bacteriological examination of water, and for the assay of the carbonic acid gas. This company filter water and soften it by well-known means, the product in regard to colour comparing very favourably with distilled water. Admirable preventive measures are also taken to provide against metallic contamination. It is needless to add that the various aerated drinks made by this company—which, by the way, included piperazine water (as a diuretic and solvent for uric acid), and phenocoll hydrochloride aerated water (of stimulant, diuretic, as well as antipyretic characters)—were so grouped as to add very materially to the attraction of this exhibit. Opposite were the clear and bright mineral waters of the Chemists' Aerated and Mineral Waters Association—known in the trade as "Camwal"—(Gifford-street, N.), whose series of huge show syphons suggested the dangers of a bombshell or their application as fire extincteurs had they been charged. The soda, potash, and lithia waters are a decided feature of this firm, which may be relied upon to supply these in accordance with B.P. requirements.

Coming now to natural mineral table waters, not the least interesting was the natural seltzer water known as Catley Abbey water, drawn from the springs in Digby, Lincs, and bottled by the Catley Abbey Natural Seltzer Water Company at that place. It is a clean-drinking, bright, sparkling water, with refreshing saline taste and exhibiting an excellent composition. It deserves to be better known, and the fact that it is a "home production" should recommend it to not a few. We might apply the same remark to the Woodhall bromo-iodine spa waters, also of Lincolnshire, which have been beneficially employed in the treatment of glandular swellings and enlarged joints. The appointments for visitors at Woodhall Spa are, we learn, excellent, and suitable recreation is abundantly provided. Apollinaris (Stratford-place, W.) is too well known to need mention, as is also the proverbially soft Johannis (Regent-street, S.W.) water, both of which formed interesting exhibits in this section. Rosbach water (Messrs. Hertz and Collingwood, Sussex-place, Leadenhall-street, E.C.) is well adapted for table purposes; it is pleasantly sparkling, clean to the palate, and may be taken with confidence as a mild and agreeable antacid. We pass to the saline purgative waters, amongst which should be mentioned Condal water (Lambeth-hill, E.C.), of soft saline taste and only very moderately bitter, the amount of sulphate of soda present in it being in much larger proportion than the corresponding magnesium salt—a fact, it is said, which has rendered it useful and valuable to those with whom magnesium salts do not so easily agree; Æsculap (Messrs. Ingram and Royle, Farringdon-street, E.C.), largely used as a purgative because of its purity and comparatively neutral taste; Friedrichshall (The Apollinaris Co., Stratford-place, W.), the new spring yielding a water of undoubted therapeutic value; a bitter purgative water recently obtained by Messrs. Hertz and Collingwood (Leadenhall-street, E.C.) from a new spring in Budapest, which is unusually rich in mineral constituents and possesses excellent active medicinal characters; Vichy water (Messrs. Ingram and Royle, Farringdon-street, E.C.), renowned in the treatment of kidney complaints and of rheumatism; Grande Grille water for diseases of the liver and biliary organs; and a few others. Home medicinal waters were represented in the exhibit of the Harrogate Corporation, the specimens shown comprising the well-known strong and mild sulphur waters, and strong and mild chalybeate and saline waters, an interesting feature of the exhibit being the specimens of the mineral salts obtained on evaporation of a definite volume of the waters just described. The excellent appointments at Harrogate and the various bath-rooms and bath appliances were shown in an excellent series of striking photographs. The Leamington Town Improvement Association exhibited specimens of the waters of Leamington Spa, the composition of which closely resembles that of many Continental waters which are of reputed medicinal worth. The accommodation and appointments of the Royal Pump-room and baths at Leamington, which were reopened a few years ago, are of admirable design and to offer every comfort to visitors. In regard to mineral waters, Messrs. F. Newbery and Sons (King Edward-street, E.C.) make "lentiforms" of Vichy and lithia which are briskly effervescent when placed in water, producing, it is said, an exact representation of the natural waters, but in accurately adjusted medicinal quantity. We have already pointed out the unique character of the Flitwick chalybeate water, which contains a large proportion of oxidised iron held delicately in solution—a fact which doubtless accounts for its marked tonic properties. It forms a pleasant and refreshing drink combined with lemonade, the combination being called "Wikko" (The Flitwick Chalybeate Co., Borough High-street, S.E.). The arsenio-ferric water drawn from the Levico Springs in the South Tyrol (Messrs. Hertz and Collingwood, Leadenhall-street, E.C.) claims attention as a valuable therapeutic agent in anæmia, chlorosis, and in some skin affections. It is supplied in two strengths, the first (strong) containing $\frac{1}{10}$th gr. of arsenious acid in the pint and 34 gr. of soluble iron salts, and the second (mild) $\frac{1}{20}$th gr. of arsenious acid and 8 gr. of iron in the pint. It is said to be readily tolerated and not to cause disturbance of the digestive functions. The same firm, we notice, are introducing an excellent bitter and stomachic in the shape of a combination of high-class, old, matured Spanish wine (Jerez) with the active principles of choice cinchona bark. It presents tonic and restorative properties in a very palatable form, and is known as Jerezcona wine. The Laurent-Perrier Sans Sucre champagne (Messrs. Hertz and Collingwood) appears to be increasing in popularity, on which we reported analytically in THE LANCET of Jan. 13th, 1894. Despite the almost complete absence of saccharine substances, it possesses all the esteemed qualities of a natural high-class wine. This important fact is evidently being appreciated, and not least by the profession. Lastly, we may add to this list the exhibit of Messrs. Alexander Riddle and Co. (Commercial-street), who undertook the exhibit of Stowers' Lime Juice Cordial and the materials used in its preparation. It is a well-known wholesome beverage, and the peculiar pleasant fragrance of the lime seems to have been imprisoned very successfully in this firm's product.

VI.—MISCELLANEOUS.

Foremost in the rapidly diminishing space at our disposal we must mention some novel apparatus which we observed connected with methods of clinical testing. Messrs. Oppenheimer (Worship-street, E.C.), for instance, have recently introduced Fehling's test for sugar in bi-palatinoid form. On simply dissolving the bi-palatinoid in hot water Fehling's standard solution is obtained, which may conveniently be employed for the detection or estimation of sugar, each bi-palatinoid containing an equivalent of copper representing a definite amount of sugar. Similarly bi-palatinoids are prepared for the detection of albumen in urine by the ferrocyanide method. Messrs. Allen and Hanburys (Plough-court, Lombard-street, E.C.) exhibited Sir George Johnson's complete test cabinet for the quantitative estimation of albumin, sugar, and urea in urine, consisting of Johnson's picro-saccharometer, Esmarch's albuminometer, urinometer, &c., together with the necessary instructions. Useful apparatus, also for the use of medical men and students, including ureasometers, albuminometers, urine-testing cabinets, and bacteriological apparatus, were

[1] Vide THE LANCET, July 21st, 1894.

Digitized by Google

amongst the manifold collection of Messrs. Southall Brothers and Barclay (Birmingham). Messrs. Hewlett and Sons (Charlotte-street, E.C.) also exhibited some excellent apparatus in the same connexion, as well as the bismuth test for sugar, the trichloracetic acid test for albumin, the peptone test for bile salts, &c. The Medical Supply Association (Teviot-place, Edinburgh) exhibited also a urinary trial case and a simple instrument for the quantitative estimation of sugar in urine. Of other exhibits not easy to classify should be mentioned that of Messrs. Dowie and Marshall (Strand), who, it is well known, have given special attention to the design of boots for various requirements. This exhibit included designs in wood showing the means adopted for the treatment of flat feet; lasts constructed for contracted feet; boots and shoes made for the treatment of hammer toe; boots and shoes with dividing sole for straightening the great toe; a newly patented bandage boot for the treatment of weak ankles and flat feet; and, lastly, a simple and effective design for separating the great toe. Messrs. Price and Co. (Battersea, S.W.) showed their well-known pure soaps and sanitary soaps, while their exhibit, as a matter of course, included their glycerine, remarkable for its admirable purity, and which has now maintained its excellence for nearly half a century. "Transpirable" vests formed the chief exhibit of the Liverpool Lint Co. (Liverpool), who showed also flax and cotton lints, bandages, domette flannels &c., cotton wools, carbolised tows, protective lint, splint padding, &c. Their "transpirable" wool goods are worthy of marked commendation, since, as undervests, chest protectors, &c., this material allows evaporation of the exhalations of the skin and will not become cold and damp, it is said, even with profuse perspiration. A thick nap or pile is raised on one side of the material, which is of the finest lambswool, making it light, warm, and comfortable, and therefore exemplarily hygienic. Clinical figures and charts and an excellent series of lantern-slide physiological studies were on view at the exhibit of Messrs. Danielsson and Co. (Beaumont-street, W.), while some space was devoted to that most useful of articles, the label, together with sundry indispensables of the same order—midwifery record books, dispensary list and calendar, general case-book, bedside record, temperature charts, date pads, and so on, all of which were shown by Messrs. Silverlock (Knightrider-street, E.C.). We cannot conclude the list without reference to the "Ceres" automatic letter and card files (Messrs. Dawson, Bream's-buildings, Chancery-lane), which relieve the practitioner of much of the burden of keeping his correspondence "in decency and in order."

VII.—LITERATURE.

Books add very little to the brilliance of an exhibition, and this may be taken to be the reason why there were few booksellers represented. Messrs. Cassell and Co. (Ludgate-hill, E.C.) exhibited their well-known and useful series of manuals for students of medicine and the new work on "A System of Surgery," by Frederick Treves, F.R.C.S. Amongst Messrs. H. K. Lewis's (Gower-street, W.C.) announcements were "A Handbook of the Theory and Practice of Medicine," by Fred. T. Roberts, M.D., B.Sc., F.R.C.P.; "On the Treatment of Pulmonary Consumption," by Vincent D. Harris, M.D., F.R.C.P. (in the press); "Dental Materia Medica and Therapeutics," by James Stocker, L.D.S. (in the press); "Handbook of Diseases of the Ear for the Use of Students and Practitioners" (just ready); and several additions to Lewis's well-known Practical Series. Amongst recent issues of Mr. F. J. Rebman should be mentioned "A System of Legal Medicine," by Allan McLane Hamilton, M.D.; "Surgical Pathology and Therapeutics," by John Collins Warren, M.D., and Lawrence Godkin; while a Pictorial Atlas of Skin Diseases and Syphilitic Affections is in course of preparation, and will be published in twelve parts (each 10*s.* 6*d.*), the publication of the first part being promised soon.

Works also in active preparation by F. J. Rebman (Adam-street, Strand) are "Obstetrics," edited by R. C. Norris (admirably illustrated); "Physiology," edited by W. H. Howell, Ph.D., M.D.; and "Water-supplies," by J. C. Thresh, M.B. Vict., Ch.B., D.P.H. Camb., D.Sc. Lond. Messrs. Young J. Pentland (West Smithfield, E.C.) also exhibited a stock of well-known works; while a useful series of books was to be found on the shelves of the exhibit of the Scientific Press, Limited (Strand).

We are asked to state that the medical, surgical, and pharmaceutical antiquities exhibited by Messrs. Oppenheimer, Son and Co., Limited, at the Victoria Rooms, Savoy Hotel, and collected for them by Dr. Luigi Sambon of Rome, are their property and were collected by Dr. Sambon in discharge of a commission.

Medical News.

UNIVERSITY OF LONDON.—INTERMEDIATE EXAMINATION IN MEDICINE.—The following candidates passed in July, 1895:—

ENTIRE EXAMINATION.

FIRST DIVISION.

Battye, Walter Rothney, B.Sc., University College, Bristol and London.
Carr, Janet Waldegrave, London School of Medicine for Women.
Hartley, Harold Owens College.
Hawker, Alice Mary, London School of Medicine for Women.
Hine, Hugh Fitz Neville, Middlesex Hospital.
Singer, Harold Douglas, St. Thomas's Hospital.
Thiele, Francis Hugo, University College.
Wood, William Bird Herapath, Mason College.

SECOND DIVISION.

Adams, Edward William, Sheffield Medical School and Firth College.
Arnold, Frank Arthur, London Hospital.
Benham, Charles Henry, University College.
Berry, Thomas Percival, Guy's Hospital.
Brickwell, Frank, St. Bartholomew's Hospital.
Broadley, John, Yorkshire College.
Bull, Stanley Arthur, Westminster Hospital.
Cleveland, Arthur John, Guy's Hospital.
Cowie, Robert Macnamara, King's College.
Davies, David Lawford Francis, Middlesex Hospital.
Field, Richard Cullingworth, Yorkshire College.
Harston, George Montagu, Charing-cross Hospital.
Hawkesworth, Thomas A., King's College.
Hirst, William James, Yorkshire College.
Jamieson, Harold Henry, St George's Hospital.
Jenkins, Herbert Stanley, University College, Bristol.
Jenkins, John David, London Hospital.
Leaning, Robert Craske, St. Mary's Hospital and Birkbeck Institute.
Leete, Frances Annie, London School of Medicine and Birkbeck Institute.
Lindsey, Colin Dunrod, St. Mary's Hospital and Birkbeck Institute.
Linton, Marion Sanford, B.A., London School of Medicine for Women.
Lloyd, Francis Seymour, St. Mary's Hospital.
Mooney, John, Owens College.
Page, John Basil, St. Mary's Hospital.
Sharman, Mary Nona, Glasgow University and London School of Medicine.
Sheldon, John Henry, Owens College.
Smallman, Arthur Britton, Owens College.
Smith, James Eckersley, University College, Liverpool.
Smith, Sidney Maynard, St. Mary's Hospital.
Swainson, James M. Graham, Westminster Hospital.
Taunton, Edgar, University College.
Telling, Walter Henry Maxwell, Guy's Hospital.
Tolputt, Arnold George, University College, Dundee, and Queen's College, Belfast.
Tyndale, Wentworth Francis, St. George's Hospital.
Watts, Eliza Turner, London School of Medicine for Women.
White, Harold Edward, Mason College.
Whitehead, Clarence Barns, St. Mary's Hospital.
Wiggins, William Denison, St. Mary's Hospital.
Williams, Percy Glyn Savours, University College.
Wilson, Alexander Gordon, London Hospital.
Wright, William, Owens College.

EXCLUDING PHYSIOLOGY.

FIRST DIVISION.

Rowe, William Trethowan, St. Bartholomew's Hospital.
Scott, Henry Harold, St. Thomas's Hospital.
Thwaites, Gilbert Bahn, St. Thomas's Hospital.
Wallis, James Garfit, London Hospital.

SECOND DIVISION.

Aveline, Henry Talbot Sidney, Bristol Medical School and Clifton Laboratory.
Belt, Francis Victor Owen, St. Bartholomew's Hospital.
Cridland, Arthur Bernard, Bristol Medical School and Clifton Laboratory.
Crisp, George Bedford, St. Mary's Hospital.
Handson, Lionel Edwin Charles, Guy's Hospital.
Jones, John Llewelyn, University College.
Mawson, Joseph Arthur, Yorkshire College.
Schölberg, Harold Alfred, St. Bartholomew's Hospital.
Smith, Sidney Robert, Westminster Hospital.
Stock, William Stuart Vernon, University College, Bristol, and Clifton Laboratory.
Whitfield, Lorenzo, Mason College.
Woodbridge, Elliot Wilson, St. Bartholomew's Hospital.

PHYSIOLOGY ONLY.

FIRST DIVISION.

Baker, Alfred Eaton, Middlesex Hospital.

SECOND DIVISION.

Barnes, John Arthur Percival, St. Bartholomew's Hospital.
Bletchly, George Playne, Middlesex Hospital.

Digitized by Google

East, William Norwood, Guy's Hospital.
Hall, Edmund Stokes, Guy's Hospital.
Hunt, Edward Lewis, St. George's Hospital.
Lansdown, Charles Ewbank, St. Mary's Hospital.
Marriage, Herbert James, St. Thomas's Hospital.
Maxwell, James Laidlaw, St. Bartholomew's Hospital.
Moore, Percy William, Guy's Hospital.
Winterburn, Joseph Williamson, St. Thomas's Hospital.

N.B.—The names of candidates who have obtained honours do not appear in the above list.

EXAMINATION FOR HONOURS.

ANATOMY.

First Class.

Fagge, Charles Herbert (Exhibition and Gold Medal), Guy's Hospital.
Walker, Frederick Edward (Gold Medal), Guy's Hospital.

Second Class.

Dewhirst, Wilfred Arthur, Yorkshire College.
Sherlock, Edward B., B.Sc., Westminster Hospital.

Third Class.

Morland, Egbert C., B.Sc., Owens College and St. Bartholomew's Hospital.
Dixon, Montague, B.Sc., University College.
Hewitt, Harry Edward, St. Thomas's Hospital.

PHYSIOLOGY AND HISTOLOGY.

First Class.

Morland, Egbert Coleby (Exhibition and Gold Medal), Owens College and St. Bartholomew's Hospital.
Kelsall, Robert (Gold Medal), Owens College.
Walker, Frederick Edward, Guy's Hospital.

Second Class.

Dobson, Joseph Faulkner, Yorkshire College.
Dykes, Campbell, University College.
Sherlock, Edward Birchall, Westminster Hospital.
Richmond, G. E., B.A., B.Sc., Guy's Hospital and King's College.

Third Class.

Cornford, Mary Frances, London School of Medicine and University College.
Turner, Philip, B.Sc., Guy's Hospital.

ORGANIC CHEMISTRY.

First Class.

Pierce, Robert Wynn Charles, B.Sc. (Exhibition and Gold Medal), St. Thomas's Hospital.

Second Class.

Turner, Philip, Guy's Hospital.
Milton, William Tayler, Guy's Hospital.
Morland, Egbert Coleby, Owens College and St. Bartholomew's Hospital.
Sherlock, Edward Birchall, Westminster Hospital.
Richmond, George Ernest, Guy's Hospital and King's College.

Third Class.

Bruce, Harold Wilson, Guy's Hospital.
Nabarro, David N., B.Sc., University College.

MATERIA MEDICA AND PHARMACEUTICAL CHEMISTRY.

First Class.

Turner, Philip (Exhibition and Gold Medal), Guy's Hospital.
*Sherlock, Edward Birchall, Westminster Hospital.
Milton, William Tayler, Guy's Hospital.
Walker, Frederick Edward, Guy's Hospital.

Second Class.

Pierce, Robert Wynn Charles, St. Thomas's Hospital.
Gardner, Thomas Hudson, King's College.
Hewitt, Harry Edward, St. Thomas's Hospital.

Third Class.

Bruce, Harold Wilson, Guy's Hospital.
Cornford, Mary Frances, London School of Medicine and University College.
Fagge, Charles Herbert, Guy's Hospital.

* Obtained the number of marks qualifying for the Exhibition.
N.B.—The bracket denotes equality of merit.

The following candidates passed the Preliminary Scientific (M.B.) Examination in July, 1895:—

ENTIRE EXAMINATION.

First Division.

Addey, William Fielding, University College.
Bailey, James Connor Maxwell, St. Bartholomew's Hospital.
Bartlett, Albert William, University College, Aberystwith.
Boeddicker, Hans Frederick William, King Edward's High School, Birmingham, and Mason College.
Bullen, Charles Henry, Mason College.
Butler, James Alfred, Guy's Hospital.
Camps, Percy William Leopold, Guy's Hospital.
English, Thomas Crisp, University Tutorial College.
Ford, Harriet Rosa Delo, Owens College.
*Greenwood, William Osborne, private study.
Hamilton, Louisa, University College.
*Hare, George William, Guy's Hospital and Blenheim House.
Johnson, Robert George, University College, Bristol.
*Jones, Bernard Watson, King Edward's High School, Birmingham, and Mason College.
Lewin, Jessie Augusta, University Tutorial College.
McDougall, Olive, Owens College.
*McGavin, Donald Johnstone, King Edward's High School, Birmingham, and Mason College.
Martin, John Ranald, Middlesex Hospital and University College.
*Mason, Edward Daniel, Mason College.
Parkinson, Arthur Stanley, Yorkshire College.
Penny, Charles Burnage, Guy's Hospital and Alwyne Institute.
Ridout, Charles Archibald Scott, St. Bartholomew's Hospital.
Roberts, Bernard H. St. Clair, University Tutorial College and private study.
Rutherford, Richard, University Tutorial College and private study.
Seccombe, John William Smyth, private study and St. George's Hospital.
Soutter, Charles Duncan, King Edward's High School, Birmingham, and Mason College.
Thackray, Christopher, Firth College.
Wilmersdoerffer, Gisela, University Tutorial College.
Wrench, Guy Theodore, Guy's Hospital.

Second Division.

Barnett, Emily Bonnycastle, Bedford College, London.
Bott, Percival George Albert, St. Mary's Hospital.
Brodribb, Charles Hildred, St. Mary's Hospital.
Carlé, Frederick Charles, King's College.
Collinson, Harold, Yorkshire College.
Cook, Lewis, Westminster Hospital and private study.
Dickson, Louis Edington, University College, Liverpool.
Edwards, Francis Robert, King Edward's High School, Birmingham, and Mason College.
*Elliott, Athol Garnet, University College.
Evans, William Thomas, University College, Cardiff.
Fox, Adam, Queen's College, Cork, and private study.
Freear, Alexander, St. Mary's Hospital.
Gale, Caroline Lilian, University College.
Greenfield, Dudley George, Guy's Hospital.
Guest, Leslie Haden, Owens College and private study.
Günther, Charles Frederick, B.A., Firth and University Colleges.
*Hampshire, Florence Elizabeth, Yorkshire College.
Hirst, Walter Clapham, Yorkshire College.
Holyoak, Ernest William, Wyggeston School.
Hunt, John William, St. Mary's School.
Ivens, Mary Hannah Frances, University Tutorial College.
Jackson, Sophia Bangham, University College, Aberystwith.
James, Henry Walter, University College, Cardiff.
John, Ambrose Hilton, St. Bartholomew's Hospital.
Jones, Ernest Williams, Mason College and private study.
*Law, William Jackson, Firth College and Kingswood School.
*Lewin, George, City of London School and University Tutorial College.
Lister, Alfred Ernest John, St. Bartholomew's Hospital.
Lloyd, Brinley Richard, University College, Cardiff.
Longhurst, Frederick William, University College and private tuition.
Marshall, James Cole, St. Bartholomew's Hospital and private tuition.
Maw, George, University College.
*May, John Percy, St. Bartholomew's Hospital and Central Foundation School.
Mooney, Annie, Owens College.
Parrott, Hugh McDowall, Guy's Hospital and Carlyon College.
Phillips, Mary Elizabeth, University College, Cardiff.
Pridham, Arthur Tregelles, St. Bartholomew's Hospital.
*Reaney, Michael Foster, London Hospital.
Reeve, Ernest Frederick, Aske's Schools, Hatcham.
Reynolds, Bryan Ellis, University Tutorial College, Birkbeck Institute, and private study.
Richardson, Catherine Mary, Durham College of Science, Newcastle-on-Tyne.
Rowntree, Hilda Mallinson, University College.
Scholefield, Harry, Owens College.
Smith, Edgar Dyke, St. Bartholomew's Hospital.
Stuart, William Lumsden, King's College.
Tattersall, John, Birkbeck Institute and University Tutorial College.
*Tchaykovsky, Barbara, North London Collegiate School and Bedford College.
Thornley, Robert Lewis, St. Bartholomew's Hospital.
Welchman, Frank Ernest, University Tutorial College and private study.
*Widdows, Sibyl Taite, Dulwich High School and University Tutorial College.
Wrigley, Philip Roscoe, Owens College.

Honours Candidates recommended for a Pass.

Fry, Walter Burgess, St. Thomas's Hospital.
*Williamson, John Samuel, St. Bartholomew's Hospital.

CHEMISTRY AND EXPERIMENTAL PHYSICS.

Amsler, Albert Maurice, St. Paul's School.
†Barron, Robert Macpherson, Guy's Hospital.
Beattie, Frederick Alexander, Guy's Hospital.
Bernstein, Julius Meyer, Owens College.
Birch, Anthony, University Tutorial College and private study.
Bonallo, William, Rutherford College, Newcastle-on-Tyne, and private study.
†Bridger, James Frederick Edmund, St. Mary's Hospital.
Brown, Herbert William, University Tutorial College.
Butcher, William James, Owens College and private study.
Caddy, Adrian, St. Paul's School.
Calcott, James Douglas Clives, Grammar School and University College, Bristol.
†Chapman, John Ellis, Firth College.
Churchill, John Aylward, University College and St. George's Hospital.
†Coleridge, Alfred, University College, Bristol, and private study.
Cope, Gilbert Edgar, Westminster Hospital and private study.
Dalnow, Samuel, Guy's Hospital and private study.
De Pass, Jeannette Rachel, Alwyne Institute.
†Dobson, Margaret Bernard, University College.
Elliott, Arthur Forbes, Oundle School.

Pickin, Frederic Harold, University College, Bristol.
Rooke, William Sidney, University College.
Savill, Philip, University College.
†Selous, Cuthbert Edmund, St. Thomas's Hospital.
Smith, Douglas Theodore, Edinburgh University and School of Medicine.
Soltau, Alfred Reginald, London Hospital.
†Stallard, Nigel [illegible], University and University Tutorial Colleges and private study.
Stannus, Hugh [illegible], St. Thomas's Hospital and private study.
†Stilwell, Archibald [illegible], private study and University Tutorial College.
Storr, Florence, Dulwich High School and University Tutorial College.
Syms, John Kendall, University College.
Trubshaw, Kenneth Vincent, Epsom College.
Ward, George Stafford, London Hospital and private study.
Wethered, Ernest, St. Bartholomew's Hospital.
Wood, Frank Herbert, St. Bartholomew's Hospital.
Wood, Maurice Dunbar, Guy's Hospital.
Wyld, Ellen Elizabeth Janet, Westfield College.

* These candidates have also passed in the Mathematics of the Intermediate Examination in Science, and have thus become admissible to the B.Sc. Examination.
† These candidates have now completed the examination.
N.B.—The names of candidates who have obtained honours do not appear in this list.

The following candidates passed the Intermediate Examination in Science (1895):—

FIRST DIVISION.

Allen, Arthur Hinton, private study.
Allen, George Pethybridge, private study and Craigmore College, Bristol.
Beale, Hanway Richard, St. Thomas's Hospital.
Beckton, Henry, Clare College, Cambridge, and University Tutorial College.
Bell, Herbert George, B.A., St. Peter's, Cambridge, University Tutorial College, and private study.
Belton, Frank, private study and Manchester Technical and Central Board Schools.
Berridge, Emily Mary, Bedford College, London, and Royal Holloway College.
Borchardt, Walter Gustav, St. John's College, Cambridge.
Borrow, Frederick Charles, St. Bartholomew's Hospital and private tuition.
Buller, Arthur Henry Reginald, Mason College.
Caudwell, Ben, B.A., private study and University Tutorial College.
Clark, John Alexander, University College, Aberystwith.
Cook, Sydney George, Sidney Sussex College, Cambridge.
Curgenven, Arthur Joseph, St. Paul's School.
Dalton, John Edwin, Yorkshire College.
Edward, James Mitchell, private study.
Forster, Martin Onslow, University Tutorial College.
Gardner, Thomas Jevons, School of Science, Kidderminster, and private study.
Godfrey, Alfred Robert, University College, Nottingham.
Hartle, Hilda Jane, King Edward's High School, Birmingham.
Harvey, Charles John, B.A., private study.
Heaton, Ellis Wright, Yorkshire College and Huddersfield Technical School.
Heitefusz, Hermann Wm. U., private study and St. John's College, Battersea.
Houghton, Robert Harold, Birkbeck Institute.
Huntly, George Nevill, private study and Royal College of Science.
Jack, George, private study and Glasgow Technical College.
Jones, Harry Walton, University College, Aberystwith.
Jones, Humphrey Owen, University College, Aberystwith.
Kent, George Joseph, University Tutorial College and private study.
Lawn, James Gunson, Royal College of Science, private study, and University Tutorial College.
Lewis, Edward Watkin, Aske's School, Hatcham.
Marshall, Bouchier M. Cole, Royal College of Science.
Matthews, Gay Frederick, private study.
Moore, Harold, Middlesbrough High School.
Morland, Helen, Croydon High School.
Neumann, Edgar David M., Balliol College, Oxford.
Nunn, Henry Thomas, University Tutorial College and private study and tuition.
Orme, Philip, University College and Polytechnic Institute.
Paramore, Richard Horace, Merchant Taylors' School, University Tutorial College, and private study.
Parkinson, Alfred Howard, private study.
Pearce, Harold, University Tutorial College.
Picknett, William Allen, Royal College of Science and University Tutorial College.
Pinchin, Ernest Alfred, Birkbeck Institute and private study.
Potts, Ernest Henry, B.A., private study and Birkbeck Institute.
Prince, Henry, Westminster Training and University Tutorial Colleges.
Richardson, Harold Ernest, B.A., private study.
Rowntree, Ernest William, Owens College.
Rylands, Louis Gordon, B.A., private study and University Tutorial College.
Sherlock, Robert Lionel, private study.
Skeats, Ernest Willington, Royal College of Science and private study.
Sprankling, Charles Henry Graham, University College, Bristol, and private study.
Watts, William Herbert, private study.
Whiting, Thomas, University College, Aberystwith.
Winckle, Edward William, King Edward's High School, Birmingham, and Mason College.
Woodhead, Francis John, Yorkshire College.
Worth, Henry John George Rogers, Yorkshire College and private study.

SECOND DIVISION.

Adams, Sophia G. Louisa, University College, Aberystwith.
Ashby, Blanche Mary, University College, Cardiff.
Battersby, Albert, private study.
Bennett, George Richard, University College, Cardiff.
Bigby, Agnes Grace Doull, Westfield College.
Bird, George Arthur, University Tutorial College, Birkbeck Institute, and private study.
Blandy, Wilfrid Boothby, High School and University College, Nottingham.
Brown, Frank William Radford, St. John's College, Green-lanes, and private study.
Brown, John, private study.
Clegg, Harold Fielding, University College, Aberystwith.

Coates, John Victor Hubert, City and Guilds Central Institute and private study.
Crosland, Zachariah Drake, Technical School, Huddersfield, and private study.
Crosskey, Alexander Nash, City and Guilds Institute and University Tutorial College.
Crossland, Cyril, Windermere Grammar School.
Daniel, Vincent, University College, Cardiff.
Drennan, William St. George, private study.
Edwards, William Buckland, private study and University Tutorial College.
Evans, David, private study and University Tutorial College.
Firth, John Shaw, Firth College.
Fuller, Frank Joseph, B.A., Fitzwilliam Hall, Cambridge University.
Gillmore, Thomas Parker, Hazlecroft, Weston-super Mare, and University College, Bristol.
Goldie, Ellis Gordon, University College, Birmingham, and private study.
Goodwill, Gustave, University Tutorial College.
Herald, Hartley Davy, private study.
Hogg, Herbert Ernest, private study.
Lambshead, William Samuel, B.A., private study and University Tutorial College.
Lathwood, Arthur, Mason College.
Lloyd, John Bennett, Haberdashers' Schools, Hoxton, University Tutorial College, and private study.
Lowndes, Louis, University College, Nottingham, and private study.
Newton, William Henry, University College, Nottingham.
Nott, Gilbert Harwood, University College, Aberystwith.
Orwin, Annie, Royal Holloway College.
Parkinson, John Harold, B.A., University College, Aberystwith.
Parsons, Arthur Ambrose, private study.
Powell, John, Goldsmiths' Institute and private study.
Rawlinson, Percy, Yorkshire College and private study.
Sheard, Gertrude, Westfield College.
Shields, Leonard, Firth College.
Smiles, Samuel, University College.
Sterling, Samuel Frederick, Battersea Polytechnic.
Watson, George, B.A., University College.

HONOURS CANDIDATES RECOMMENDED FOR A PASS.

Aston, Stafford, University College and private tuition.
Briggs, John, private tuition and University College.
Hall, Emma, Royal Holloway College.
Hodgson, Stanley, Guy's Hospital.
Jackson, Henry, Downing College, Cambridge, and Bury Grammar School.
Laws, Arthur Robert, Durham College of Science, Newcastle-on-Tyne.
Ormond, Sidney James, Guy's Hospital and University Tutorial College.

N.B.—The names of candidates who have obtained honours do not appear in this list.

EXAMINATION FOR HONOURS (INTERMEDIATE SCIENCE AND PRELIMINARY SCIENTIFIC (M.B.) CONJOINTLY).

INORGANIC CHEMISTRY.

FIRST CLASS.

Parrish, Samuel, Int. Sc. (disqualified by age for the Exhibition), Royal College of Science, Yorkshire College, and private study.
‡Hill, Charles Alexander, Prel. Sc., Pharmaceutical Society, King's College, St. Thomas's Hospital, and private study.
Howard, Albert, Int. Sc., Royal College of Science.
‡Wynn, William Henry, Prel. Sc., Mason College and private study.

SECOND CLASS.

Miller, Ernest Alfred, Int. Sc., Guy's Hospital.

THIRD CLASS.

Morgan, David J., Prel. Sc., St. John's College, Cambridge.
Dixon, Edwin Henry, Int. Sc., Merchant Venturers' Technical College, Bristol.
Platt, P. Polding, Int. Sc., private study.
Clark, Ernest, Int. Sc., Firth College and Central Hall of Science, Sheffield.
‡Mankiker, R., Prel. Sc., University College and private study.
Humphrey, Edith E., Int. Sc., Bedford College, London.
More, Andrew, Int. Sc., Royal College of Science, University Tutorial College, and private study.

EXPERIMENTAL PHYSICS.

FIRST CLASS.

Starling, Sydney George, Int. Sc. (Neil Arnott Exhibition and Medal), Royal College of Science and University Tutorial College.
*†Melton, G. R., Int. Sc., Royal College of Science, University Tutorial College, and private study.

SECOND CLASS.

Drysdale, Charles V., Int. Sc., Finsbury and City Guilds, Birkbeck Institute, and private study.

THIRD CLASS.

Brooks, Ernest E., Int. Sc., private study.
Adams, Walter, Int. Sc., Firth College.
Griffith, Owen W., Int. Sc., University College, Bangor.
Whitin, Paul I., Int. Sc., King Edward's School, Birmingham, and Mason College.
Whittington, H. W., Int. Sc., Sheffield Royal Grammar School and Firth College.

BOTANY.

FIRST CLASS.

Freeman, William George, Int. Sc. (Exhibition), Royal College of Science and St. Olave's Grammar School.

SECOND CLASS.

‡Sollas, Igerna B. J., Prel. Sc., Royal College of Science, Dublin, and Alexandra College.

THIRD CLASS.

Terry, Herbert, Prel. Sc., Owens College.

ZOOLOGY.

FIRST CLASS.

‡Kelly, Agnes, Preliminary Science (Exhibition), University and Bedford Colleges, London.
Lindsey, A. B., Prel. Sc., University, St. Thomas's Hospital, and Birkbeck Institute.

SECOND CLASS.

Singer, Charles Joseph, Prel. Sc., University College.
‡Sollas, I. B. J., Prel. Sc., Royal College of Science, Dublin, and Alexandra College.
Scroggie, W. R. J., Prel. Sc., Islington High School and Birkbeck Institute.

THIRD CLASS.

Savage, T. C., Prel. Sc., University College.

* Obtained the number of marks qualifying for the Exhibition.
† Disqualified by age for a "Neil Arnott" Medal.
‡ These candidates have also passed in the Mathematics of the Intermediate Examination in Science, and have thus become admissible to the B.Sc. examination.
N.B.—The bracket denotes equality of merit.

UNIVERSITY OF EDINBURGH.—On Aug. 1st the following candidates were recommended to receive the degrees named below:—

THE DEGREE OF DOCTOR OF MEDICINE.

†Allison, J., M.B., C.M.
*Anderson, J. S., M.B., C.M.
Anderson-Berry, D., M.B., C.M.
Barnes, A. R., M.B.
Battersby, J. H., M.B., C.M.
Bond, C. H., M.B., C.M.
†Cameron, G. C., M.B., C.M.
Carruthers, E. J. W., M.B., C.M.
Clayton, J. S., M.B., C.M.
Connor, F. G., M.B., C.M.
Crawford, W. T., M.A., M.B., C.M.
*Davies, R., M.B., C.M.
Dennison, A., M.B., C.M.
*Dickson, G., M.B., C.M.
†Dixon, C. J. W., M.B., C.M.
Doughty, D. S., M.B., C.M.
*Dow, D. R., M.A., M.B., C.M.
†Dunlop, J. C., M.B., C.M.
‡Ehrke, F. L., M.B., C.M.
Fairweather, D., M.A., M.B., C.M.
Forsyth, E., M.B., C.M.
*George, F. J., M.B., C.M.
*Giles, A. B., M.B., C.M.
*Gladstone, H. B., M.B., C.M.
Gordon, H. L., M.B., C.M.
*Grant, J. T., M.B., C.M.
Green, V., M.B., C.M.
*Grosvenor, W. C., M.A., M.B., C.M.
Hill, J. S., M.B., C.M.
†Home, G., M.B., C.M.
Home, W. B., B.Sc., M.B., C.M.
†Horne, R. M., M.B., C.M.
Hughes, T. B., M.B., C.M.
Jameson, G. B., M.B., C.M.
†Jareja, Sir Bhagvat Sinhji, M.B., C.M.
†Johnston, G. F., M.B., C.M.
*Jones, W. W., M.B., C.M.
Knaggs, W. H. E., M.B., C.M.
‡Koch, W. V. M., M.B., C.M.
Lambert, J. R. P., M.B., C.M.
Lishman, F., M.B., C.M.
*Lyle, F. W., M.B., C.M.
†Macalister, C. J., M.B., C.M.
*Macdonald, J. M.A., M.B., C.M.
†Mackay, F. W., M.B., C.M.
*MacLelland, R., M.B., C.M.
Macleod, H. W. G., M.B., C.M.
*Macnaughton, G. W. F., M.B., C.M.
Martin, E. F., M.B., C.M.
*Moorhouse, J. H., M.A., M.B., C.M.
Morris, S. G., M.B., C.M.
*Morrison, G. E., M.B., C.M.
*Murray, W., M.B., C.M.
†Newman, G., M.B., C.M.
Ogilvy-Ramsay, M., M.A., M.B., C.M.

THE DEGREE OF MASTER IN SURGERY.

Martin, E. F., M.D.

§ With first-class honours.
‖ With second-class honours.

Thesis Gold Medallists.—F. L. Ehrke, M.D.; W. V. M. Koch, M.D.; J. Ritchie, M.D.; A. Walker, M.D.

The following awards have been made:—The Ettles Scholarship, J. E. Bowes; the Beaney Prize in Anatomy and Surgery, W. J. Garbutt; the Murchison Memorial Scholarship in Clinical Medicine, N. Macvicar; the Goodsir Memorial Prize, G. Mann; the Gunning Victoria Jubilee Prize in Obstetrics, A. Walker; the Gunning Victoria Jubilee Prize in Public Health, G. Newman; the Gunning Victoria Jubilee Prize in Zoology, J. D. F. Gilchrist; the Buchanan Scholarship in Gynæcology, W. W. Chipman; the James Scott Scholarship in Midwifery, D. J. Graham; the Milner Fothergill Medal in Therapeutics, E. M. Smith, M.D.; the Cameron Prize in Therapeutics, Professor Behring; and the Edinburgh University London Club Prize, R. Hutchison.

UNSOUND FRUIT.—An enormous number of unsound greengages have been seized at a jam factory in the East-end of London and condemned.

BEQUESTS AND DONATIONS TO HOSPITALS.—Mrs. Sarah Meadows, of Aylestone Hill, Hereford, has sent a donation of £500 to the general fund of the Hereford Infirmary, and £500 to be invested as a fund for incurables, such fund to take her name.—The late Mr. John Bell Sedgwick, of St. Andrews-place, Regent's-park, London, has bequeathed £200 to the Middlesex Hospital.—Her Majesty the Queen has sent a donation of £100 to the building fund of the Royal Free Hospital, Gray's Inn-road, London.—The Treasurer of the French Hospital and Dispensary, Shaftesbury-avenue, London, has received £1000 from M. Robert Lebaudy.—The Mercers' Livery Company has sent a further donation of 100 guineas towards the rebuilding of the front of the Royal Free Hospital, Gray's Inn-road, London.—The late Mr. Woodfindin, of Kenwood Bank, Sharrow, Sheffield, has bequeathed £400 to the Sheffield Public Hospital, £200 to the Children's Hospital, and *inter alia* two-thirds of the residue of his real and personal estate are to be used in the erection, equipment, and endowment of a convalescent home, to be called the "George Woodfindin Convalescent Home."—The governors of the Haywood Hospital, Burslem, have received a donation of £100 from Mr. S. Round, of Cheddleton.—The late Mr. William Berry of Manchester has bequeathed £10,000 to the Manchester Infirmary, £2000 to the Southport Convalescent Hospital, and £1000 to the Royal Eye Hospital, Manchester.—The Merchant Taylors' Company has contributed 20 guineas to the new building fund of the Royal Ear Hospital, Soho-square, London.—Sir John Williams, Bart., M.D., has contributed £250 to the rebuilding fund of the North London or University College Hospital, Gower-street.—Mr. Henry Yates Thompson has sent on behalf of his mother, Mrs. Thompson of Thingwall, £200 towards the endowment fund of the Crewe Memorial Cottage Hospital, and the Earl of Crewe has contributed £100 towards the same fund.

PRESENTATIONS.—Dr. A. Smith of Whickham, Newcastle-on-Tyne, has been presented by the members of the Whickham Ambulance Association with a carved oak settee, bearing a suitable inscription, in recognition of his services as their lecturer.—On the occasion of their golden wedding Mr. W. U. Buée of Slough and Mrs. Buée have received from their friends and neighbours a most gratifying token of esteem and regard. A committee of residents in Slough and its neighbourhood was recently formed to consider the terms of the presentation, and at its final meeting, presided over by the Rector of Slough, reported that the scheme had been very favourably regarded by the public. As a substantial result of the support which they had received the committee purchased the lease of the house in which Mr. Buée had so long resided for the remainder of the lives of himself and his wife, and money was also invested in Consols in their names. In order to spare Mr. and Mrs. Buée the fatigue incidental to a meeting at the Town Hall, it was resolved that the presentation should be made by a deputation of three persons only, and this part of the proceedings was accordingly carried out at Mr. Buée's house on Aug. 10th. The address, which bore upwards of 270 signatures, was illuminated on vellum and framed. After it had been read and the other documents handed over, Mr. Buée responded on behalf of himself, his wife, and their daughters, acknowledging the gratification which they felt at the manifestation of so much kindness on the part of their friends.

FOREIGN UNIVERSITY INTELLIGENCE.—*Berlin:* Dr. Bonhoff, Assistant in the Hygienic Institute, has been recognised as *privat-docent* in Hygiene.—*Breslau:* The Extraordinary Professorship of Ear and Throat Diseases, has been offered to Dr. Siebenmann of Basle, who has declined it on the ground that there is no clinic to supply the necessary teaching material, and that he would, therefore, have had to take some means of collecting patients himself.—*Erlangen:* Dr. Zelenka, Professor of Zoology, has resigned his chair for the purpose of undertaking a long scientific expedition in remote regions.—*Giessen:* Professor Strahl of Marburg has been appointed as successor to Professor Bonnet in the chair of Anatomy, he having gone to Greifswald in place of Professor Sommer, whose health has unfortunately obliged him to retire.—*Halle:* Dr. D. Ackermann, Professor of Pathological Anatomy, is about to retire, his chair being taken by Dr. Eberth, Professor of Normal Anatomy, and formerly Professor of Pathological Anatomy in Zurich. To the chair of Normal Anatomy Professor Roux of Innsbrück has been appointed.—*Königsberg:* Dr. Franz Meschede has been promoted to an Extraordinary Professorship of Psychiatrics. Dr. Gerber has been recognised as *privat-docent* in Throat and Ear Diseases.—*Tübingen:* Dr. Kallius of Göttingen has been appointed Extraordinary Professor of Anatomy in place of Dr. Froriep, who has been promoted to the ordinary professorship, in succession to Professor Henke, retired.—*Prague:* Professor Rollet of Gratz is expected to be the new Professor of Physiology.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The Case of Dr. Herz.

A MEMORIAL for presentation to the Prime Minister with reference to the case of Dr. Herz has been prepared by Sir Edward Reed, and is receiving the signatures of Members of Parliament. The memorial says that no treaty can justly or reasonably be held to bind the Government of this country to a course of conduct which was never contemplated by the Extradition Treaty, and which must be repugnant to the feelings of both the French and English nations, because it cannot be further prolonged without the infliction of certain death. Even if every offence alleged against Dr. Herz had been proved,

Digitized by Google

instead of being alleged only, it would nevertheless by this time, after so prolonged a period of imprisonment, have become a public duty, says the memorial, to solicit the intervention of Her Majesty's Government for the termination of the custody in which Dr. Herz has so long been held.

The Drains of the House of Commons.

Representations have been made to the First Commissioner of Works with reference to the state of the drains of the House of Commons during the hot weather, and Mr. Akers Douglas is having special inquiries made with a view to any defects being remedied.

HOUSE OF LORDS.

THURSDAY, AUG. 15TH.

Teaching University for London.

Earl Cowper, Chairman of the Royal Commission on this subject, addressed the House with regard to it in the course of the debate on the address. Everybody, he said, was agreed that it was a positive disgrace that the great population of London was not possessed of that which almost every capital in Europe possessed—a great teaching university, because they could not call by that name the University of London, which was merely an examining board, well as it did its work and eminent as were the people connected with it, and which, in spite of its name, had no more to do with London than it had to do with the rest of the United Kingdom. What was wanted was that for which for years thinking people have been striving—namely, that there should be a proper and economical system of teaching which would apply to poor as well as to rich, and which would conduct the student from point to point up to that final examination which could only be considered as the crowning of the whole, and by which the stamp of a completed education would be conferred. The plan proposed by the Commission of which he had the honour to be chairman had received the support of all the bodies interested in the question, and he urged the Government to act on the report of that Commission without any further delay.—The Duke of Devonshire, Lord President of the Council, said in reply that in the present circumstances of the situation the Government intend to proceed now with no legislative measures except such as were absolutely necessary for carrying on the business of the country. Like their predecessors, the present Government were strongly convinced of the desirability and even of the necessity of meeting the views which had been expressed in favour of the establishment of a Teaching University for London. His noble friend had mentioned the unanimity with which the present scheme had been received by many important bodies in the country, but he had passed over somewhat lightly the strong objection taken to the scheme by a large and not unimportant section of Convocation. It had not been possible for any of his colleagues to look into this matter very closely, and he was afraid that, as it was impossible to legislate at present, it would be premature on his part to commit the Government wholly to the scheme in the shape proposed by the Commission of his noble friend. He could only assure him that the subject would receive careful attention on the part of the Government before Parliament met again for legislative business.

HOUSE OF COMMONS.

FRIDAY, AUG. 16TH.

Cattle Disease.

A number of questions were addressed to Mr. Walter Long, the new President of the Board of Agriculture, with reference to the exclusion of Canadian live cattle from this country. Mr. Long, in his reply, said he was aware that in certain districts it was desired to admit the cattle, but the question was one which he was bound to consider from the point of view of the interest of agriculturists generally, which, in his opinion, imperatively required that every possible safeguard should be taken against the introduction of disease. So recently as the 10th ult. two animals landed in this country from Canada were found to be affected with pleuro-pneumonia, and in view of this fact and of all the circumstances disclosed in the printed papers which had been laid before the House he had no alternative but to maintain in force the requirement that Canadian cattle should be slaughtered at the port of landing.

East London and its Water-supply.

Mr. Chaplin, President of the Local Government Board, answering questions on this subject, said it had been a matter of much regret to him that so large a proportion of the inhabitants, and many of them the poorest, of the district included in the limits of supply of the East London Water Company had been put to very serious inconvenience by the limitation of the hours during which a supply was obtainable, and, as he could not but feel that a continuance of this limitation of the supply might be attended with danger to the public health, the condition of things had caused him some anxiety, and the matter had been receiving his constant attention. The difficulty in which the company had been placed had been occasioned by the exceptional drought which existed until very recently and the insufficiency of the means of storage possessed by the company. The company had in a large number of streets set up standpipes attached to the mains, which were constantly charged with water, and this had, no doubt, been very helpful to a large number of persons when the ordinary supply was cut off. Allegations had been made as to a very serious increase in the mortality in the district of the water company, but he had caused inquiries to be made on this subject in connexion with the returns of the Registrar-General, and he was glad to be able to state that, so far as means of comparison exist, it would appear that the mortality of the district supplied by the company had not been greater than in districts within the limits of supply of other companies where there had been no deficiency in the water-supply. As regards the statutory obligation of the company to give a constant supply, he must point out that by Section 15 of the Metropolis Water Act, 1871, it was provided that a company should not be subject to any liability for not giving a constant supply when the want of such supply arose from unusual drought or other unavoidable cause or accident. He was glad to be able to state that he was informed by the company that they found that through the recent rains they might now safely extend the hours of supply from to-morrow, and that water would be turned on at about six in the morning and left on until about five in the afternoon daily.

Provision for the Aged Poor.

Mr. Balfour, First Lord of the Treasury, said, in answer to a question by Mr. Channing, that the Government were in favour of a further investigation into the various schemes for making provision for the aged poor, and the principles on which it should be conducted were now under their consideration.

TUESDAY, AUG. 20TH.

The University of Wales.

The Chancellor of the Exchequer, replying to a question by Mr. Brynmor Jones, said that a grant of £3000 was made for the preliminary expenses of the University of Wales last year, and he understood that as this sum was insufficient for the purpose, and his predecessor promised a further grant of the same amount in the present year, a vote for that sum would be taken in a supplementary estimate.

The Marking of Foreign Goods.

Mr. Ritchie, President of the Board of Trade, undertook to consider the question of strengthening the Merchandise Marks Act and the regulations made under it, and invited members to supply him with information of cases where the law appeared to be evaded.

Health of the Mediterranean Squadron.

In response to a request for the latest information as to the health of the Mediterranean Squadron, Mr. Goschen, First Lord of the Admiralty, said that on Aug. 13th the Commander-in-Chief telegraphed that it was perfectly satisfactory.

BURRIDGE, J. W., L.R.C.P., L.R.C.S., L.M. Edin., has been reappointed Honorary Surgeon to the Lewes Dispensary and Infirmary and Victoria Hospital.

CLENDINNEN, W. M., M.R.C.S. Eng., L.R.C.P. Lond., has been appointed Medical Officer of No. 3 Sedgley District, Dudley Union, vice J. G. Clendinnen, deceased.

CROSSKEY, W. F., M.D., C.M. Glasg., has been reappointed Honorary Consulting Surgeon to the Lewes Dispensary and Infirmary and Victoria Hospital.

EMSON, A., L.R.C.P., L.R.C.S. Edin., has been appointed Medical Officer to the Union Workhouse and the Dorchester Sanitary District.

FAWSSETT, F., M.B. Lond., B.S., L.R.C.P., M.R.C.S., has been re-appointed Honorary Surgeon to the Lewes Dispensary and Infirmary and Victoria Hospital.

HALL, P. A., L.R.C.P. Lond., M.R.C.S., has been reappointed Honorary Surgeon to the Lewes Dispensary and Infirmary and Victoria Hospital.

HILL, GEORGE, L.R.C.P., L.R.C.S. Edin., has been appointed Medical Officer of Health for the Holme Cultram Urban Sanitary District.

HOUGHTON, L. F., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the Second Sanitary District of the Liskeard Union.

JAGO, R. O., M.R.C.S., has been appointed Medical Officer of Health for the Irlam Urban Sanitary District.

KINGDON, E. C., M.B., M.R.C.S., has been appointed Honorary Surgeon to the Nottingham Eye Infirmary.

LAIRD, F., L.R.C.P., L.R.C.S. Edin., has been appointed Medical Officer for the Ravensthorpe Sanitary District of the Dewsbury Union.

LAMB, WM., M.D., C.M. Edin., has been appointed Medical Officer of Health by the Arnold District Council.

LASLETT, MAURICE H., M.R.C.S. Eng., L.R.C.P. Lond., has been appointed Junior Assistant Medical Officer to the Somerset and Bath Lunatic Asylum.

MACKEITH, A. A., M.B., C.M. Glasg., has been appointed Medical Officer for the Seventh Sanitary District of the Barnstaple Union.

MASON, A. H., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the Walton Sanitary District of the Chertsey Union.

NAIRN, R. W., M.B., C.M. Glasg., has been appointed Medical Officer for the Farnsfield Sanitary District of the Southwell Union.

NASH, W. G., L.R.C.P., F.R.C.S., M.B., has been appointed Medical Officer for the No. 7 Sanitary District of the Market Harborough Union.

NASON, W. S., M.B., C.M. Edin., has been appointed Medical Officer for the Workhouse of the Nuneaton Union.

O'SULLIVAN, M., M.B., B.Ch. Irel., has been appointed Medical Officer to the Medical Aid Society for the C, D, and G Divisions of the Dublin Metropolitan Police.

PEARCE, J. P., M.R.C.S., has been reappointed Honorary Surgeon to the Lewes Dispensary and Infirmary and Victoria Hospital.

PERKINS, HENRY CAMPBELL, M.R.C.S., L.R.C.P., has been appointed Medical Officer to the Nayar Brigade, Travancore, Madras.

POOLE, S., M.B., C.M. Edin., has been appointed a District Medical Officer for the Wolverhampton Union.

ROOSE, R., M.D. Brux., L.R.C.P., L.M., L.R.C.S. Edin., M.R.C.S., has been appointed Medical Attendant to the Turkish Embassy in London.

SMITH, R. W. INNES, M.B. Edin., has been appointed Assistant House Surgeon at Ancoats Infirmary, Manchester.

SMYTHE, L., M.D. Glasg., F.R.C.S. Eng., has been reappointed Honorary Consulting Surgeon to the Lewes Dispensary and Infirmary and Victoria Hospital.

TAYLOR, J., M.D., C.M. Aberd., D.P.H. Camb., has been appointed Medical Officer of Health for the Chester-le-street Rural Sanitary District.

TEMPLEMAN, CHAS., M.D., C.M. Edin., D.Sc. (Public Health), has been appointed Medical Officer to the Town Council and Burgh of Dundee.

THOMAS, J. P., L.R.C.P., L.R.C.S., L.M. Edin., has been appointed Medical Officer of Health and Medical Attendant at the Sanatorium by the Lowestoft Town Council.

TURNER, G. J. K., M.B., C.M. Aberd., has been appointed Medical Officer for the No. 4 Sanitary District of the Chipping Norton Union.

WALKER, F. H. R. J. U., L.S.A., has been appointed Medical Officer for the Coleford Sanitary District of the Frome Union.

WILLETT, EDGAR, M.B. Oxon., F.R.C.S., has been appointed an Additional Non-resident Anæsthetist to St. Bartholomew's Hospital.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL, Gray's-inn-road.—Clinical Assistants.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, Victoria-park, E.—Assistant Physician.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, Victoria-park, E.—House Physician for six months. Board and residence, and allowance for washing provided.

GENERAL HOSPITAL FOR SICK CHILDREN, Pendlebury, Manchester.—Junior Resident Medical Officer for one year. Salary £80 per annum, with board and lodging.

GENERAL HOSPITAL, Nottingham.—House Physician for two years. Salary £100, rising £10 a year to £120. Also Assistant House-Surgeon for six months. Board, lodging, and washing in the hospital provided.

MANCHESTER CLINICAL HOSPITAL FOR WOMEN AND CHILDREN, Park-place, Cheetham-hill-road.—House Surgeon. Salary £80 per annum, with apartments and board. Applications to Mr. H. Teague, Secretary, 38, Barton-arcade, Manchester.

WEST RIDING ASYLUM, Wadsley, near Sheffield.—Fifth Assistant Medical Officer. Salary £100 per annum, rising £10 a year up to £150, with board, &c.

Births, Marriages, and Deaths.

BIRTHS.

BENSON.—On Aug. 14th, at Grosmont, Pantsilas, R.S.O., the wife of H. P. D'Arcy Benson, M.B., Ch.M., of a son.

BURD.—On Aug. 19th, at Castle House, Shrewsbury, the wife of E. Lycett Burd, M.D. Cantab., of a son.

CORNELIUS.—On Aug. 11th, at Compton-road, N., the wife of Walter Cornelius, M.B. Lond., of twin daughters.

EUSTACE.—On Aug. 11th, at Weston-super-Mare, the wife of E. Eustace, M.D. Durh., of a son.

KNOX.—On Aug. 13th, at East Molesey, the wife of J. J. Knox, M.A., M.B. Cantab., of a daughter.

LIGHTFOOT.—On Aug. 21st, at St. Matthew's-terrace, Leyburn, R.S.O., Yorks, the wife of J. P. Lightfoot, M.R.C.S. Eng., L.R.C.P. Lond., of a son.

ORMEROD.—On Aug. 17th, at 26, Devonshire-terrace, Hyde-park, W., the wife of Charles E. Ormerod, M.D., of a son.

POWELL.—On Aug. 14th, at Pirbright, Surrey, the wife of Surgeon-Captain S. Powell, M.B. Irel., Army Medical Staff, of a daughter.

SEQUEIRA.—On Aug. 16th, at Branksome, Bolingbroke-grove, Wandsworth-common, the wife of G. W. Sequeira, M.R.C.S. Eng., of Aldgate and Streatham, of a daughter.

WHITESTONE.—On Aug. 13th, at Hollingbourne, Kent, the wife of Augustus M. Whitestone, M.B. Dubl., of a son.

MARRIAGES.

EVANS—DIXON.—On Aug. 21st, at All Saints, Wribbenhall, Kidderminster, by the Rev. F. R. Evans, assisted by the Rev. H. Brierley and the Rev. A. Dickins, Oliver Conrad Penrhys Evans, M.D., of Kidderminster, youngest son of the late Colonel H. W. Evans, to Ethel Martha (Patty), daughter of Henry Dixon, Esq., J.P., of Wribbenhall. No cards.

FOTHERGILL—WOON.—On Aug. 15th, at St. Luke's, Chelsea, W. E. Fothergill, M.A., B.Sc., M.B., C.M. Edin., of Manchester, to Edith Alberta, third daughter of J. Dillon Woon, Esq.

HOLDEN—SIKES.—On Aug. 13th, at St. Peter's Church, Sudbury, John Sinclair Holden, M.D. Irel., of Sudbury, to Mary Agnes, eldest daughter of the late John Sikes, Esq., of Sudbury, Suffolk.

STANLEY—HACON.—On Aug. 14th, at the Parish Church of St. John-at-Hackney, Hubert Stanley, B.A., M.B. Camb., M.R.C.S., L.R.C.P., of Brabourne, Kent, to Emily Laura, youngest daughter of Edward Dennis Hacon, F.R.C.S., of Hackney.

YOUNG—WHITE RICKARD.—On Aug. 15th, at S. Columb Minor, Alfred H. Young, M.B., F.R.C.S., of the Owens College, Manchester, to Caroline Davy, daughter of the late R. White Rickard, of The Bays, Putney, and New Quay, Cornwall. No cards.

DEATHS.

BRISTOWE.—On Aug. 20th, at Dixton Vicarage, Monmouth, John Syer Bristowe, M.D., LL.D., F.R.S., F.R.C.P., Consulting Physician to St. Thomas's Hospital, of Old Burlington-street, aged 68.

CORNWALL.—On Aug. 12th, at Glastonbury, John Cornwall, M.R.C.S., in his 79th year.

THOMPSON.—On Aug. 8th, at Exeter, George Thompson, M.D., for nearly twenty years Medical Superintendent of the City and County Asylum, Stapleton, Bristol, aged 52.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

EDITORIAL NOTICE.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICE.

"THE LANCET" AND ACCIDENT INSURANCE.

A LITHOGRAPHED CIRCULAR LETTER, emanating from an office in the Strand district, is being sent to members of the medical profession, offering to supply them with THE LANCET, in conjunction with an accident insurance policy. The Proprietors of THE LANCET are in no way connected with the scheme (of which they cannot approve), and were not aware of its inception until their attention was called to it by a reader who had received the circular.

THE LATE SIR WILLIAM SAVORY, BART., F.R.S., &c.

MESSRS. BAILLIÈRE, TINDALL, AND COX have sent us a copy of a photogravure by the Swan Electric Engraving Co., from a photograph by Messrs. Barraud, which they have published of the late Sir William Savory. It is extremely well executed and an admirable portrait. The published price is half a guinea.

J. G., M.B., C.M.—Polyorchidism has frequently been diagnosed during life, but only one case (two testicles on one side) has been found on post-mortem examination, and in this case there was no microscopic verification of the nature of the supposed additional testicle. Orth's Handbook of Pathological Anatomy contains an account of this case.

Civis Colonix.—In answer to a question addressed to our readers last week two correspondents have recommended that communication should be opened with "Cheiron," 460, Oxford-street, W.

PENSIONS TO POOR-LAW MEDICAL OFFICERS.

To the Editors of THE LANCET.

SIRS,—Kindly inform me through your correspondence columns under what Act of Parliament a board of guardians may grant a retiring pension to a district medical officer, what proportion it may bear to the former salary, and whether a practitioner of fifty-five years of age and a continuous service of twenty-nine years would be eligible for it.

I am, Sirs, yours faithfully,

Aug. 7th, 1895. AN OLD SERVANT.

*** The Act of Parliament relating to superannuation is Vict 29, c. 31. The candidate for full superannuation—namely, two-thirds of his salary—must be sixty years of age and have spent forty years in the Poor-law service. Retirement after ten years' service entitles the Poor-law medical officer to ten-sixtieths of his salary, with an addition of one-sixtieth in respect to each additional year of service until a maximum of forty-sixtieths (or two thirds) be reached.—ED. L.

MEDICAL TITLES.

To the Editors of THE LANCET.

SIRS,—I am a mere licentiate of a College of Physicians and of a College of Surgeons. My doorplate bears the modest inscription Mr. ——, Surgeon. By a recent legal decision it is doubtful whether a licentiate of a College of Physicians has the right to call himself a physician. If this be true it is obvious that the same ruling must hold good in the case of a licentiate of a College of Surgeons. Must I erase the word "surgeon" from my plate, and if so what am I to substitute?

I am, Sirs, yours faithfully,

Aug. 18th, 1895. A MERE LICENTIATE.

THE UTILISATION OF THE LABOUR OF INMATES OF WORKHOUSES.

A CORRESPONDENT makes the following suggestion to us:—

"The utilisation of pauper labour without injury to the labour market appears to be a difficult problem. But there are some channels into which it could be turned with advantage to the working community. For example, a free day-nursery for the children of women who have to work would be a great boon to those poor mothers. There are thousands of widows, deserted wives, and other women who are compelled to support themselves by working out of their homes. They are often greatly handicapped by having very young children, for whose care some provision is, with difficulty, made out of the small wages they earn so hardly. The poor-houses might not be the fittest possible place, but they are better than the streets. No doubt a free nursery would be a gain not only to the mothers of the children but to the ratepayers. It would diminish sickness and accidents among the children, and it would enable women, who now have to take their children into the house, to live outside on their own earnings. But, even if it cost a little, money could not be better spent than in helping those who are willing to do their utmost to keep off the rates."

As is the case with so many kindly and philanthropic proposals there is as much to be said against this one as for it. The proper management of day-nurseries and *crèches* is an exceedingly difficult thing, and it is not very likely that many of the unfortunate derelict women our correspondent refers to would be able to bring to their task any of the qualities necessary for its proper performance, and the risk of the spread of disease would be increased. Again, a free day-nursery would have the objection of all entirely free things. The really hardworking and self-respecting would be inclined to look down upon an institution as open to their idle and dissolute sisters as to themselves, while the thoroughly worthless would make of the charity almost a permanent home for their children. The States of New York and Massachusetts have done more systematic work in this direction, we believe, than any of the countries in Europe and, if our correspondent is interested in the question he cannot do better than write to the New York Board of Charities or the Boston Children's Aid Society for information.

M.B., C.M.—Our correspondent asks our advice so that he may "know how to act should such things occur again." We hope they never may, for they disclose a lamentable state of affairs, but should they, it will be, in our opinion, his best, though his most disagreeable course to disregard his fellow-practitioner entirely—to treat him as one who has placed himself in a situation where the calls of etiquette cannot be worth listening to. His duty will be towards the patient, not his patient strictly, but a sufferer.

A QUESTION OF SALARY FOR MEDICAL OFFICERS OF HEALTH.

To the Editors of THE LANCET.

SIRS,—I am medical officer of health to a rural district council, and I have been requested to formulate a scale of fees for attendance and medicine at the isolation hospital, which is a mile and a half from my residence. The appointment most probably would be permanent, and the administration would devolve on me. The number of patients would vary, and at times there would not be any. What are the usual fees charged; or what could be considered reasonable fees?

I am, Sirs, yours faithfully,

Aug. 19th, 1895. INQUIRER.

*** No general rule can be laid down; but a fixed salary should be given for the general medical control and supervision of the establishment, and the amount of this must necessarily depend upon the distance of the hospital from the writer's residence, the nature of the resident hospital staff, the number of beds, and the frequency of the use of the hospital. To this should be added a fee for attendance on each patient who is not, at his or her own cost, attended by another medical practitioner. The amount of this will, of course, depend upon the fees generally paid in the locality, and the fee should be less when multiple hospital patients are seen at one visit than when journeys have to be paid to see a single hospital patient. But the scale of fees should be fixed in advance, the medical attendant taking the chance of the several attacks being lengthy and troublesome or of short duration and trivial.—ED. L.

Inquirer's communication is receiving attention.

FROZEN SECTIONS.

To the Editors of THE LANCET.

SIRS.—Can any of your readers inform me where I could get any information about frozen sections (say, of brain)? Also what is the best work on brain localisation? I am, Sirs, yours thankfully.

July 20th, 1895. COLONIAL.

*** Information as to the preparation of sections by freezing and other methods will be found in Colman's "Section Cutting and Staining," Goodall's "Microscopical Examination of the Human Brain," and similar works. "Functions of the Brain," by Dr. Ferrier, and the chapter on Localisation in Dr. Gowers' "Manual of Diseases of the Nervous System" contain very complete information upon the subject of brain localisation.—ED. L.

"PROPER FACILITIES TO THE CORONER."

To the Editors of THE LANCET.

SIRS,—I beg to thank you for your prompt reply to my question in your last issue; but from the opinion expressed in the following part of your sentence I must say that I very strongly dissent, as I think most of my medical brethren will also. The coroner (non-medical, I may state) for this district—and probably the same might be said of many others—seems to be decidedly averse to calling professional witnesses if he can by any means avoid doing so. Though inquests have been held on several cases in which, to my mind, the medical evidence was a most important item, our coroner has always decided not to summon the medical man. Now, without, of course, wishing to outstep the province of the medical practitioner, I would simply point out that it is a gross injustice to any medical man that he should be requested to politely "give a coroner previously to the inquest every proper information within his power," and thus, of course, obviate the necessity of his being summoned. I grant that a great deal of explanation may possibly rest in the interpretation of your word "proper," your definition of which term I should like to see. But I know that, for my own part, I should consider myself "very ill-advised" indeed to give gratis to any person, coroner or any other, professional information for which I am honourably and legally entitled to receive one guinea. Personally, I am not at all anxious to appear in coroners' courts more frequently than is absolutely necessary, but I do think that it is most dishonouring and degrading to our profession that its members should be thus quietly and privately induced to give away freely and gratuitously, as if it were worth nothing, that which is of legally recognised high value, is their own exclusive right as members of the profession, and should be duly prized accordingly. It seems needless for me to add that we have, of course, no claim for remuneration unless under summons, and all other information given is, apparently, never expected to be charged for.

I am, Sirs, yours faithfully,

Aug. 19th, 1895. MEDICUS.

*** Our correspondent's inference is by no means warranted. He placed before us a general case, not a special one, and the information that the coroner in a particular district is a layman and averse to calling professional witnesses has nothing to do with his previous communication. Our reply was based on what we were asked, not on what we did not know. "Proper" information means, of course, general information to be given to a fellow citizen discharging a civic duty, not particular scientific information which the medical man would do well to withhold until upon his oath before the coroner. Such courtesy as we have suggested as advisable between a coroner and a medical man, whatever the profession or proclivities of the coroner, so far from obviating the necessity of summoning the medical man, would in many doubtful cases lead directly to that course. We are perfectly alive to the high value of medical evidence at inquests, as the records of our columns from year to year amply demonstrate. We must add that our correspondent is somewhat unjust as well as illogical in thus (thoughtlessly no doubt) suggesting that we would recommend the adoption of any course of action "dishonouring and degrading to our profession."—ED. L.

Subscriber.—The most correct method is to print the name as follows:—Mr. A—— B——, M.B., C.M. This should defy criticism.

W. S. must pass at least the two final examinations required for the Paris M.D. degree.

M. V.—We cannot insert the letter. We do not recommend individual practitioners.

"UNQUALIFIED PRACTICE."

To the Editors of THE LANCET.

SIRS,—There is one aspect of the question to which I have seen no reference yet in all the discussions. I require someone to do my dispensing, and to attend to anything while I am on my rounds, also to make the "harmless, necessary" perfunctory calls which many of my old poor patients so much enjoy. Of course I refer to the visits between the essential ones. For these purposes, I have always found a young gentleman fresh from the hospital, and reading for his diploma, fully competent. In deference, however, to the growing feeling against unqualified assistants, I am willing to pay the market price for a qualified man, though his time would hang rather heavily, as I prefer to do the visiting myself. In response to my advertisement, only three qualified men applied. One was in Ireland, two far off for a personal interview, and the others were considerably over forty years of age, and therefore, from my point of view, unsuitable. I am, Sirs, yours truly,

Aug. 16th, 1895. PRINCIPAL.

To the Editors of THE LANCET.

SIRS,—In THE LANCET of Aug. 17th appears a letter signed "Justitia," complaining of the great evil which exists amongst us of unqualified practice. Beneath it you add a note expressing your opinion that the General Medical Council is always ready to act in cases of covering and unqualified practice. May I be allowed to respectfully differ from you in this particular? Some distance from me is a branch surgery far away from the principal, carried on by a resident unqualified assistant, who signs death certificates right and left and otherwise acts as only one "sine diploma" dares. Some two years ago I wrote to the General Medical Council informing it of this flagrant misconduct, and gave three cases, with names and addresses, of persons who had been attended by the unqualified man and had died, the death certificates being signed by the principal, who in neither case had seen the patient, without the slightest trouble. The only satisfaction I got was a request to procure statutory declarations—by which, I suppose affidavits were meant—presumably at my own expense, and, far worse, that of courting publicity in the matter. Naturally this course was not quite to my mind; so I let the matter rest, and have heard nothing since, and the same kind of practice flourishes to-day. This is the "readiness to act" you so confidently put forward.—I am, Sirs, yours faithfully,

Aug. 20th, 1895. NON SEQUITUR.

*** The General Medical Council possesses no machinery for collecting evidence, and does not exist for such purposes. Our correspondent will find it ready to act when a case such as he details is brought forward properly substantiated. No tribunal can do more; for the Council is a disciplinary court, not a detective body.—ED. L.

RAILWAY TRANSPORT FOR INVALIDS.

To the Editors of THE LANCET.

SIRS,—A reward was offered a short time ago in a London daily for "the best and simplest method by which an invalid can be transported by rail so as to receive absolutely no jolting." The advertiser's signature was anonymous, and the offer emanated from a foreign address. Would any of your subscribers be kind enough to state anything they know about this offer or its result? If a satisfactory and winning method was obtained by this means from some competitor in England for use abroad, some of us at home would like to know of it, as some satisfactory and simple method has been for a long time much desired. I have been unable to gather anything concerning the result of the offer by other means, so I trust that some of your subscribers may help me.

I am, Sirs, yours truly,

Aug. 18th, 1895. RAILWAY.

METEOROLOGICAL READINGS.

(Taken daily at 8.30 a.m. by Steward's Instruments.)

SAVORY & MOORE'S
BEST FOOD FOR INFANTS.

The attention of the Medical Profession is especially requested to the following characteristics of this old-established **SELF-DIGESTING** *Food, which has so thoroughly maintained its reputation for superiority during an experience of 30 years :—*

Ratio of Albuminoids to carbohydrates. The ratio of the albuminoids to the carbohydrates is the same as in human milk—viz., 1 to 6·4; the ratio in cow's milk being only 1 to 3·8.

Albuminoids easy of digestion, not predigested. The albuminoids are not predigested as in pancreatised foods, but are rendered easy of digestion, leaving (as in human milk) just sufficient work to strengthen and develop the immature digestive powers, instead of weakening and abrogating them by keeping them inactive. Sir WILLIAM ROBERTS' experiments in feeding kittens show that distinct failure of nutrition occurs when the milk is predigested (peptonised), and the same thing has been observed in feeding infants, probably owing, as THE LANCET points out, to atrophy of unemployed glands.

Healthy nature of evacuations. As a consequence of the foregoing the proper peristaltic action of the bowels is maintained, and the healthy nature of the evacuations of infants fed on this food is a satisfactory feature much and favourably commented on by Mothers and Nurses.

The curdling of Cow's milk prevented. When mixed with cow's milk it prevents the troublesome curdling in the stomach which takes place when cow's milk is given alone, and assimilates its composition to that of human milk.

Complete conversion of the starch. The active Malt Diastase present provides for the rapid and complete conversion of the starch at the time of mixing into the soluble assimilable products of maltose and dextrine. The point of the gelatinisation (thickening) of the Food—viz., 140° F.—is just that at which Malt Diastase is most active, and the conversion of the starch is consequently the work of a very few minutes only.

Retention of the Phosphates and Fat. The retention of the fat and of the phosphates of the wheat and malt, which are so essential to bone formation. These exist chiefly in the outer portions of the grain, the very parts which some manufacturers pride themselves upon so successfully rejecting.

Absence of Fermentable sugar. The absence of the fermentable sugar, which in the various malt extracts and milk foods so often gives rise to Diarrhœa and Flatulence.

Verdict of Jury as to inferiority of imitations. It is the *only* Infants' Malted Food which obtained a Gold Medal at the International Health Exhibition, the Jury being comprised of such authorities as Dr. ATTFIELD, F.R.S.; G. W. WIGNER, F.I.C., the then President of the Society of Public Analysts; Dr. JAMES BELL, F.R.S., the Head of the Government Laboratories; and other distinguished Medical and English and Foreign Experts. This affords significant indication of the value to be attached to the numerous imitations, which, whilst pirating the descriptive notices of the Food, utterly fail to approach its standard of excellence.

SAVORY & MOORE,
143, NEW BOND STREET, LONDON, W.

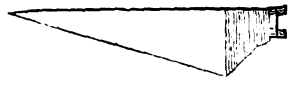
Clinical Lectures
ON
DISEASES OF THE EYE.



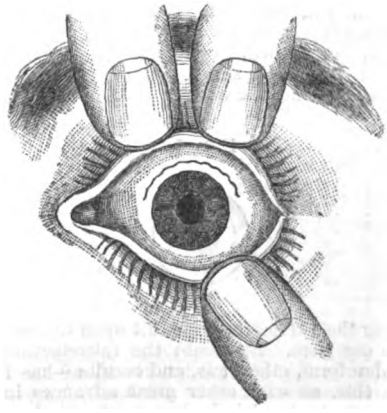
By CHARLES BELL TAYLOR, M.D.,
F.R.C.S. EDIN.,
HON. SURGEON TO THE NOTTINGHAM AND MIDLAND EYE INFIRMARY.

LECTURE XI.[1]

THE ACCIDENTS OF EXTRACTION.

MR. PRESIDENT AND GENTLEMEN,—When Von Moltke was asked by what criterion he would judge of the capacity of a general in warfare he said, "He must be tried by the touchstone of disaster"; and I think you will agree with me that it is so in surgery—that it is the accidents, the unforeseen casualties, the sinister contingencies, which tax our resources, which test our skill, which tend to perfect our manipulations, and which enable us at last to triumph over difficulties and dangers which, but for such special practice, must have proved insuperable. Let us see now what are the accidents, the difficulties, and the dangers most likely to beset us during and after the process of cataract extraction; what may be done towards their prevention; and how best to deal with them when, in spite of our care, they threaten destruction to our patients. It is now upwards of two centuries since Wenzel endeavoured to improve upon the ancient method of reclination and depression by opening the cornea with scissors and actually removing the lens from the eye; and it is nearly 150 years since Daviel presented his celebrated memoir on "Extraction à lambeau" to the French Academy of Medicine. Daviel was followed by Beer, who invented the knife (Fig. 1)

FIG. 1.



which is known by his name, and both these eminent surgeons made a flap of one-half or more of the cornea, delivering the lens through the natural pupil—an operation which, when successful, certainly left nothing to be desired; but the drawbacks, the accidents, the difficulties and dangers were so numerous, so ever-present, and so frequently fatal, that Beer is reported to have said that he "spoilt a hatfull of eyes before he could save one."[2] In fact, it was exceedingly difficult to make the incision when seated on a chair, facing a sensitive patient who was also seated—the position assumed by Daviel and his successors—or in any way to keep the flap in position; it was constantly falling into folds and frequently became retracted or even reflected upon itself. The vitreous, too, was prone to protrude or to escape in quantity sometimes, followed by hæmorrhage, so that I have more than once heard in the midst of an operation Dupuytren's historic exclamation, "L'œil est perdu." Moreover, even when the extraction was satisfactorily accomplished accidents were frequent. The iris was very apt to prolapse, the flap to become infiltrated in whole or in part, or the eyeball to suppurate; even when matters were not so bad as this there was, in a large proportion of cases, much pain, constitutional irritation, and protracted recovery, so that many blind persons refused operation altogether, and operators were very chary of interfering with patients who had the least sight remaining in either eye, so that if the worst did come to the worst they were in a position to exclaim, with the Thane of Cawdor, "Thou canst not say I did it." All these accidents of extraction were only to be successfully counteracted or avoided by great skill, practice, and foresight on the part of the surgeon, and even the best operators, as the late Mr. Critchett has remarked, "if they would only deal quite honestly with themselves, would have to record cases that, in spite of all their care and all their skill, had given them such an amount of anxiety as to neutralise, and more than neutralise, the satisfaction they derived from their successful cases." Such was the *status quo* with regard to the capital operation of ophthalmic surgery when Waldau, the late Von Graefe's assistant, having noticed that iridectomies were hardly ever followed by any ill consequences, suddenly proposed to excise a portion of iris through a small incision, and to scoop out cataracts with a spoon. Here was a glimpse of heaven! "*Hic est quem quæris.*" No flap to turn down; no iris to prolapse; no wound that could be forced open by post-chloroform sickness, or likely to be damaged by the indocility or stupidity of the patient. But, alas, "Man never is, but always to be, blessed." It was soon discovered that Waldau's procedure was no more free from distressing flaws than any other cataract operation; it was found, for instance, that it was quite inapplicable in certain forms of hard senile cataract; that it was often impossible to insinuate Waldau's scoop between the cataractous lens and the hyaloid fossa without rupturing the hyaloid membrane and setting the vitreous free; that the lens was apt to be dislocated by the spoon, and pushed down into the vitreous chamber, where it had in whole or in part (when possible) to be fished out, to the manifest damage of the eye; that a certain amount of bruising and stretching was inevitable; and that persistent iritis, with the formation of dense secondary cataract, were among the consequences of the traumatism caused by the introduction of such a formidable weapon as Waldau's spoon, with its steep edges, into the interior of the eye. Hence, although the operation survived for a time in this country, specially (with modifications) in the practice of Messrs. Bowman and Critchett, it speedily fell into disuse on the Continent, and ultimately

FIG. 2.

FIG. 3.

only bore fruit in the hands of Von Graefe, who, having visited this country in order to see Mr. Critchett's modification of Waldau's traction instrument, returned to Berlin and forthwith devised his celebrated method of linear extraction. Von Graefe's aim was to dispense with the spoon by enlarging Waldau's incision, and to extract the lens without making a flap, and in order to attain this end he invented a knife (Fig. 2); placed his incision much further back than Waldau's (Fig. 3); excised the iris and delivered the lens behind the artificial pupil. The advantages claimed for this operation were: (1) that the sclerotic, which was

[1] Delivered before the Nottingham Medico-Chirurgical Society on Jan. 2nd, 1895. Lectures I. to X. were published in THE LANCET of Sept. 5th, 1885; May 8th, June 26th, and Sept. 4th, 1886; April 16th and 23rd, 1887; Sept. 10th and Dec. 24th, 1887; Dec. 15th and 22nd, 1888; Nov. 8th, 1890; July 1st, 1893; and Aug. 18th, 1894, respectively.

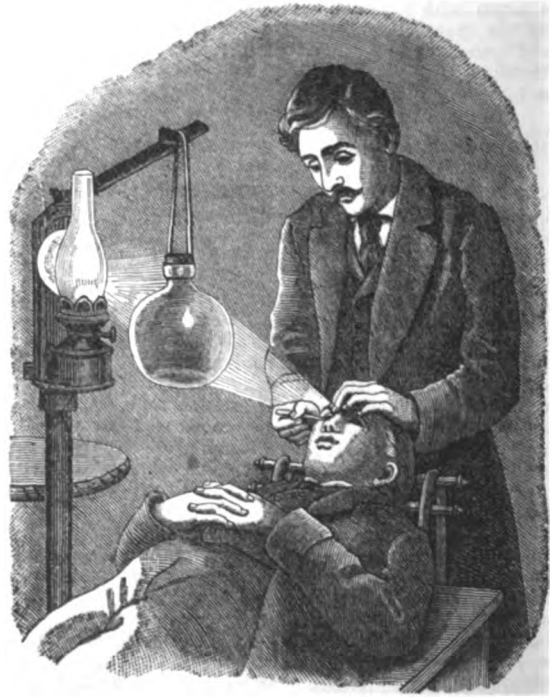
[2] "If we take into consideration the great and internal difficulties of the operation itself as he (Beer) performed it, we shall come to the conclusion that the statement is not very far from the truth."—"Practical Remarks on the Treatment of Cataract," by the late George Critchett.

Digitized by Google

alone incised, was much less likely to suppurate than the cornea; (2) that the elasticity of the tissues in this situation, and the linear character of the wound, rendered separation of its edges almost impossible; and (3) it was contended that the conjunctival flap or overlay would prove a potent safeguard against microbial infection. But the very large iridectomy necessary with this form of incision was a palpable objection. The close approximation of the edges of the wound impeded the exit of the lens, hæmorrhage often complicated the extraction, the vitreous often escaped, and iritis, iridocyclitis, and sympathetic ophthalmia were more frequent with this than with almost any other cataract operation; hence it was speedily evident that Graefe's operation pure and simple could never be anything but a *pis aller* in certain exceptional cases.[3] Nevertheless, it survived in name, but in name only, and in the hands of various operators speedily resolved itself into a mere enlargement of Waldau's incision at each extremity of the wound, just sufficient to enable the surgeon, while retaining the iridectomy, to dispense with the spoon; and this operation, which I adopted before Von Graefe's suggestion was heard of, is the operation *par excellence* with most ophthalmic surgeons to-day. The advantages claimed for it are—that it obviates bruising of the iris, prevents prolapse of the iris, facilitates the exit of the lens, forms a means of escape for the aqueous humour, which in gushing out might otherwise force the iris between the lips of the wound, and reduces the necessity for secondary operations to a minimum. But this operation also has its special accidents, its difficulties, its drawbacks, and its dangers. For instance, the extent of the wounded surface is doubled by the excision of the iris; the pain of the iridectomy is apt to provoke spasm and dangerous resistance on the part of the patient; the iris is always more or less trapped at the extremities of the wound; the exposure of the uveal track, bleeding and prolapse of the capsule between the lips of the incision—all of which are likely to happen—are to be deprecated; while the excision of the iris is fatal to the perfection of the eye.

How are we to prevent or avoid these accidents, these complications, these drawbacks to a method of extraction which is regarded by so many ophthalmic surgeons as the premier operation for cataract to-day? Well, they are to be avoided, and with the greatest ease, by simply enlarging Waldau's incision a little further, and dispensing, not only with the spoon, *but also with the iridectomy*. Now, Gentlemen, that is the operation which I venture to assure you will take the place of all others as the operation *par excellence* in all ordinary cases of cataract. Its supreme excellence is its simplicity, and in order that you may appreciate that excellence I propose to perform the operation in your presence; to show you in the persons of numerous patients who have undergone *double* extraction by this method what splendid results may be attained by it; and lastly to point out to you how the accidents, the difficulties, and the dangers sometimes attendant upon it may be counteracted, controlled, or avoided. The operation, as you see, is extremely simple: it is merely a short flap upwards (Fig. 4), and the wonder is that our predecessors

FIG. 4.



when making the old flap had not hit upon this modification long before our time. No doubt the introduction of anæsthetics—chloroform, ether, gas, and cocaine—has had much to do with this, as with other great advances in surgery. You must be sure, when about it, to make the incision large enough, and to locate it in the corneo-sclerotic junction; any invasion of the fibrous tissue of the sclerotic entails the disadvantages of Graefe's operation, and encroachment upon the cornea is to be deprecated, as wounds in this situation are apt to spoil the normal curve, do not heal so readily, and are frequently the cause of annoying anterior synechiæ.[4] When the wound is made with precision in the position I have indicated, the flap fits like a watch glass, does not override the stump, as is otherwise so frequently the case,[5] and normal conditions are so completely restored, even immediately on the completion of the operation, that fluids when dropped into the conjunctival sac do not penetrate into the anterior chamber except by the usual process of endosmosis. My knife will be found the best for making the incision, and the facility with which the right hand may be used for the left eye, with this modification of Graefe's or Linhart's pattern, is undoubtedly a great advantage (Fig. 5).

FIG. 5.

I always use a lamp for the purpose of illumination, and the facility with which instruments and other appliances may be in a moment sterilised by the hot air flowing from the chimney is not its least advantage (Fig. 6). Unlike many operators, I prefer to incise the capsule with the flame-shaped cystotome rather than with the knife, as it passes across the anterior chamber, and, as a rule, to confine the incision to the periphery of the capsule, on a level with the equator of the lens. When the capsule is incised slight pressure will cause the lens to revolve upon its axis and to present at the pupil, which it slowly dilates, prior to emerging, followed by a mass of cortex. The iris may then be replaced by gentle massage through the

FIG. 6.

closed lids, and the *status quo* maintained by the imposition of a borated pad. If the cataract does not stir on pressure after completion of the capsulotomy

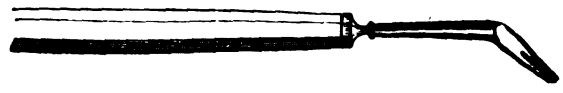
[3] For instance, when one eye has been lost after extraction from malnutrition of the cornea in an old, thin subject, with white hair, hard arteries, and wrinkled, silky skin, the other has a better chance of salvation with a linear incision well back and confined to the fibrous tissue of the sclerotic.

[4] "At the time when I operated on all kinds of cataract without iridectomy I believed at first that prolapse of the iris could be prevented by making a corneal incision like Liebreich's. This was an error from which I promptly recovered, thereafter carrying the entire wound to the vicinity of the edge of the cornea. Prolapse and impaction of the iris are less frequent when this is done, without counting other advantages of the peripheral corneal incision."—Landolt: Cataract Operation in Our Day, p. 158.—"The Transactions of the American Medical Association, 1887, furnish an argument in favour of the flap operation, specially against turning the edge of the knife forward in completing the incision."—Ophthalmic Record, July, 1894.

[5] See Becker and Norris's Atlas of the Pathological Anatomy of the Eye.

Digitized by Google

the opening in the capsule is insufficient, the lens larger than supposed, the iris too rigid or adherent, or the corneal wound too small, or the crystalline itself so shrunken as to be uninfluenced by any pressure which may safely be brought to bear, in which case the capsule must be re-incised, the corneal wound enlarged, iridectomy performed, or the cataract removed with a scoop. The results to be obtained by this operation are simply perfect. I have been in the habit of performing it for years, and as with a large practice one sometimes fails to recognise former patients, I find it now and then exceedingly difficult to say whether any operation has been performed or not. Let me illustrate my meaning. A short time ago a farm labourer, aged, gaunt, and weather-beaten, applied to me for treatment on account of catarrhal conjunctivitis affecting both eyes. He had managed to get wet through on his way to the infirmary, did not seem to mind it, and said he had been much exposed to wind and rain both night and day during the then recent lambing season. I satisfied myself that there was no iritis or other deep-seated mischief; treated him accordingly as an out-patient, and he was speedily discharged cured. Later he reappeared in order to solicit my attention to a friend who, he said, was suffering from short sight. This man I found was the subject of congenital cataract, and suggested that he should submit to operation. "Aye, you do," exclaimed patient No. 1; "I have, and it don't hurt a bit." "No, my friend," I said, "you only had inflammation from cold; that has nothing to do with cataract." "Oh, but I had, though," he replied; "you took cataracts off both my eyes six years ago; don't you remember? I was blind; my daughter used to lead me to your surgery." I said, "Where are your spectacles?" "Oh," he replied, "I never use them now without I want to read a bit at night." And this was true; I had operated on him—both eyes at one sitting—years ago, and although I examined his eyes when prescribing for the catarrhal affection I failed to see anything to remind me of what had been done.



Now, Gentlemen, that is the perfection of art—to conceal art—and I think you will agree with me that while such results are to be attained modern science will never be satisfied with anything less. The instance I have cited is not a peculiar, special, or picked case; I shall show you to-night many cases of double extraction with perfect corneæ and central and movable pupils, and they could be multiplied by the score. Of course, the operation is, as a rule, completed without misadventure, but you must not suppose that this method of extraction, any more than any other surgical procedure, is free from its peculiar accidents, difficulties, and drawbacks. For instance, the lens—as you are doubtless aware—in certain cataractous subjects is apt to become considerably swollen during the process of opacification,[6] and this increase of bulk, as you can readily understand, causes it to encroach upon the anterior chamber, displaces the iris forwards, and renders it exceedingly difficult to incise the cornea in the way I have indicated without wounding that membrane. You may complete the puncture and counter-puncture, but the moment you commence to cut upwards the aqueous escapes, the iris folds over the edge of the blade, and it seems as though you must inevitably either slice off a piece and so spoil the result, or withdraw the knife and postpone the operation. It was this difficulty and danger which led Beer to the adoption of his wedge-shaped keratome, a knife he was enabled to push steadily onwards without any to-and-fro movement, and so retain the aqueous; and it is the same difficulty and danger which is now leading so many ophthalmic surgeons to abandon the last remnant of Graefe's operation—the narrow knife—and resort to Beer's or some imitation of it.[7] I have used Beer's knife and similarly shaped instruments of my own devising, some of which have been adopted by my ophthalmic friends (Fig. 7); but there is one great objection to them all: you are compelled with these wedge-shaped knives to confine the incision to the cornea, and are not able with them to make a wound anywhere with extreme precision. I therefore advise you to adhere to the narrow knife modified according to my pattern, and when the iris folds over the edge of the blade to cut round with the hilt in the corneo-sclerotic junction. In this way any unintentional wounding of that membrane may be avoided, an accident which may be again forestalled by making a shallow incision close to the upper margin of the pupil, and enlarging it after completion of the section at either extremity with scissors; or

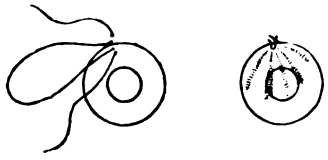
FIG. 7.

the operation may be completed with scissors alone, or the section finished with my secondary knife (Fig. 8). The wound with scissors heals readily enough, but you are compelled with them to encroach more upon the cornea than I think either necessary or desirable. Of course, retention of the aqueous is a great safeguard against the folding over of the iris upon the edge of the blade; but, inasmuch as with the narrow knife any evil effects may be readily counteracted, I cannot consider—as some writers do—

FIG. 8.

its premature escape as a formidable accident. It is different, however, when the tissues are so altered that the vitreous in an equally fluid condition drains away, and is followed by complete collapse of the eyeball. When the tissues are in this diseased condition, operative interference, unless conducted with great care, is apt to be followed by disastrous consequences. Here is a case in point. Some time ago I was asked to operate upon a man close on fifty years of age who had been all his life nearly blind from congenital cataract. The right eye had been operated on elsewhere and was, unfortunately, completely lost; nevertheless, as the left seemed favourable for operation I proceeded to extract *secundum artem*. No sooner, however, had I completed the counter puncture than the eyeball visibly shrunk and collapsed, falling into deep wrinkles and receding within the orbit. I immediately withdrew the knife and closed the eye with a borated pad, telling the patient the operation was over. Notwithstanding the slight and incomplete wound inflicted the most intense reaction followed; the eyelid became so swollen that I was obliged to divide the external canthus, to clip away folds of chemosed conjunctiva, to leech, freeze, and paint with nitrate of silver in order to stave off death of tissue from excessive inflammation. The responsibility in such cases is tremendous, and although "de l'audace" is sometimes a good motto, "cavendo tutus" with such patients is far better. I can recall three or four similar cases, and although you may say that I ought to have known that the vitreous was fluid before I commenced the operation I can assure you that it is impossible in many cases to diagnose this condition beforehand. A tremulous iris is, of course, an indication; but one may have a fluid vitreous without a tremulous iris and a tremulous iris without a fluid vitreous. Moreover, a tremulous iris has been observed when only a portion of the vitreous—that within the area of the retina—has been fluid The collapsed eyeball fallen back in the orbit, shrunk, wrinkled, and not much larger sometimes than the end of the finger, has a ghastly appearance; but I have seen the tissues of both eyes completely collapsed without any displacement of their relative positions, detached retina, or separation of choroid from the sclerotic. I have known the whole contents of the vitreous chamber to escape and twelve hours later the chamber to be refilled with fluid, and ultimately good vision restored. Escape of the vitreous, when it is of normal consistence or firmer than natural, entails separation of the tunics of the eyeball, is a much more serious accident, and is an indication of increased tension, which should have been ascertained beforehand and dealt with by iridectomy some time before extraction, or by myotics, or both. In these cases the moment the incision is completed the iris bulges and the cataract bursts through the suspensory ligament, or when the capsule is opened the vitreous gushes out, the patient

[6] This swollen condition sometimes precedes the formation of cataract, and we find patients greatly advanced in years suddenly, to the astonishment of everybody, regain the power of reading without spectacles, a phenomenon which may be also due to weakening of the suspensory ligament and dislocation of the lens forwards.



[7] Dr. Graddy, for instance, in his address before the Nashville Academy of Medicine, said: "I think it is only a question of a short time whether we shall all return to the broad knife and classic flap operation slightly modified."

Digitized by Google

groans with pain referred to the head and caused by displacement of the ciliary nerves, the vitreous is followed by blood, attempts to retain the tissues and fluids *in situ* by pressure are frustrated by vomiting, straining, or uncontrollable agitation on the part of the patient, the retina and choroid become detached from the sclerotic, and we are sometimes compelled to perform excision of the eyeball at once.

Vitreous may escape with the cataract, or immediately after its removal, owing to straining of the patient—I have seen the major portion of the contents of the eyeball deliberately squeezed out in this way; nevertheless, considerable escape of vitreous may occur and yet all go well. I have known this accident to happen, much to my chagrin, in one eye when both were operated on at one sitting, and the apparently damaged organ ultimately proved the better of the two. Of course, all pressure must be at once removed if this accident occurs, and the lens, if necessary, dipped out with a spoon. Partial dislocation of the lens, which sometimes occurs from undue pressure with a too small wound, may be righted by slight manipulation upon the closed lids and temporary occlusion of the eye. In this way escape of vitreous with possibly detached retina and formation of opacities may be avoided. The introduction of the knife with the cutting edge wrongly placed has been dwelt upon as one of the accidents incidental to this operation, but with an extremely narrow blade the event is of no importance, as it may be readily turned in any desired direction. With regard to accidents *after* extraction, prolapse of the iris is the most frequent and most important of these; it occurs in from 5 to 10 per cent. of all cases and may give rise to considerable irritation or even inflammation. This accident may be prevented by suturing the cornea—a suggestion first made by Dr. Williams of Boston, U.S., adopted by Suarez de Mendoza of Angers, and at present practised by Dr. Kalt of Paris. I have tried the suture, but, according to my experience, it is scarcely ever required. It complicates and prolongs the operation, is in itself a source of irritation, and is not always quite successful in preventing prolapse. Dr. Kalt passes the thread before making the incision, drawing out a loop so as to avoid its severance during the operation.[8] (Fig. 9.)

FIG. 9.

I think the best method of dealing with prolapse, when it does occur, is to leave it alone; according to my experience it disappears spontaneously and ultimately entails no greater defect than would have been occasioned by an iridectomy in the same situation. If, however, the prolapse should be large, and the pupil consequently drawn inconveniently upwards, an iridectomy downwards will generally suffice to restore useful vision. In ordinary cases, and when the patient appears to be fairly healthy, the exigencies of practice often compel me to operate, *séance tenante*, upon the day I see the patient for the first time, and often at my private surgery, the patient walking afterwards to the Infirmary, a distance of five hundred yards; so that my results have been somewhat severely tested. Any uncomfortable feeling after operation, as a rule, passes away, and the patients return home within a week.

If there should be pain, however, and it should last three or four hours, it is well—"Venienti occurite morbo"—to combat it at once by the injection of one-eighth of a grain of morphia under the skin of the corresponding temple. Dr. Smith of Detroit injects one-quarter of a grain as a routine practice, in order, he says, to prevent prolapse by securing contraction of the pupil. I should, however, be afraid from my experience of morphia injections to use so large a dose without tentative experiments upon the patient beforehand. Any continued pain must be looked upon as a formidable symptom and must be met at once with repeated morphia injections, ice or hot fomentations, leeches, or bleeding from the arm; the latter was Graefe's practice, and it is believed that in this way commencing suppuration may be arrested. When one has the opportunity of observing the patient some time before operating it is a good plan to try the effect of a bandage. If this sets up conjunctivitis—and in old persons it is apt to do so—it is well to treat the eye for a short time before doing anything, and to wait until the conjunctiva presents the white, glistening appearance of health before any operative interference. Obstructions in the lacrymal and nasal ducts should also be dealt with, otherwise the wound may be infected by the discharge. In spite of improved methods of procedure and thorough asepsis, and so far as possible antisepsis, and, indeed, without any special constitutional defect, suppuration now and then occurs.[9] According to Mr. Treacher Collins this is more common in old people than in young; but the tendency is greater, so he says, between the sixtieth and seventieth years than between the seventieth and eightieth years, although it is greater between the eightieth and ninetieth years than between the sixtieth and seventieth years. I have operated upon two patients over ninety years who did well, and upon a great number of patients aged eighty and upwards. Many of these have very white hair, thin skins, and rigid arteries, and one must not be surprised if the cornea collapses the moment the lens escapes without any loss of vitreous, or if it falls inwards and assumes a concave form, exactly like a tiny bird's-nest. If the wound, however, is made in the corneo-sclerotic junction, perpendicular to the antero-posterior axis of the eyeball, the flap is maintained accurately *in situ*, and no ill consequences need be feared.

Many persons suppose that, if aged persons are operated upon, the restored sight is likely to be imperfect or not to last; that, however, is not my experience, as hundreds of patients can testify. Seventeen years ago I operated upon the late *doyen* of the medical profession whose recent death has caused much comment in the medical press. I operated upon him in his eightieth year, and at ninety-seven he could see well enough to read and write as well as anyone, and with his own hand indited an essay on Longevity in the Fens. Sight so perfect at such an advanced age naturally was the subject of remark, though the commentators were evidently not aware of the fact that he had been operated on for cataract seventeen years ago. If conjunctivitis should come on after the operation it should be treated by leeches, astringents, and nitrate of silver. None of these, so far as my experience goes, interferes with the healing of the wound, though I am aware—I had it from his own lips—that Graefe had a great dread of leeches when applied to the temple within three or four days of the operation. Delirium sometimes comes on after extraction; it was not infrequent when atropine was freely used after removal of the lens. I have seen a patient so excited by the misuse of atropine that he removed the pads from his eyes and got under the bed, setting his attendants at defiance and dictating terms of surrender from this coign of vantage. No small proportion of the accidents which occur after extraction are attributable to constitutional dyscrasia on the part of the patient. I have known the healing of the wound delayed for months by an obstinate skin affection, and a similar effect to result from imprudence in an alcoholic; I have known diabetes entail suppuration after an ideally perfect operation accompanied by the most rigid asepsis and antisepsis. Gout, syphilis, and rheumatism may prove disturbing elements and need attention, while the danger of auto-inoculation from intestinal sepsis must be carefully guarded against. Putrefaction may be prevented by antiseptics, just as they will preserve meat; but antiseptics are not omnipotent, and we must never forget that healthy tissue is fatal to the microbes on which infection depends; a high state of health, too, will prevent excessive reaction or uncontrollable inflammation. The authorities of the prize-ring are well aware that by augmenting the general health they reduce the risk of sudden incapacity from injury almost to nothing. "Hit him hard, he won't swell," perhaps expresses in fewest words what I wish to convey. The poet Armstrong tells us to—

> "Couch cataracts on a day so fair
> That not a cloud disturbs the air";

but I may say that it is not wise to select what is termed "bad keeping weather" for operations.

> "When meat won't keep sweet,
> Then don't opereete."

[8] The woodcuts are from his paper on the subject, translated by Knapp and published in his Archives.

[9] Panas says that he has got rid of suppuration by injecting the anterior chamber of the eye with saturated solution of boracic acid. "A partir de cette époque nos opérés ont été à l'abri, non seulement de la panophthalmie, mais la réaction post-opératoire est devenue presque nulle."—Traité des Maladies des Yeux, tome 1, p. 580.

You will perceive that I am no advocate for the indiscriminate adoption of iridectomy in all cases of extraction, but I must again warn you that you will commit a grave error if you neglect this precaution in all cases of glaucomatous tension. Excision of the iris may also be practised some weeks before extraction—as has been recently done by Landolt in the case of Jules Simon—in persons of great age, very feeble health, or when the chances of success are small or the interests at stake very large. In order to secure success in any operation we must foresee what may happen and vary our procedure accordingly. The First Napoleon used to say, "Si je parais prêt à tout, à répondre à tout, à faire face à tout, c'est parce que, avant de rien entreprendre, j'ai longtemps médité, j'ai prévu ce qui pourrait arriver." "He foresaw what might happen." Let us take a leaf out of the book of the greatest military commander and most renowned despot of the century, and if we may not hope for rank and titles such as are freely bestowed upon our friends of the Camp, the Bar, or the Senate, let us console ourselves with the reflection that our lives are spent in endeavouring to do good, in prolonging life, in diminishing suffering, and last, but not least, in restoring sight to our fellows.

Nottingham.

NOTES ON SIX CASES OF CENTRAL RESPIRATORY PARALYSIS.

BY F. J. T. SAWKINS, M.B., CH.M. SYD.,
MEDICAL SUPERINTENDENT OF PRINCE ALFRED HOSPITAL, SYDNEY;
AND
A. S. VALLACK, M.B., CH.M. SYD.,
LATE ASSISTANT MEDICAL SUPERINTENDENT, PRINCE ALFRED HOSPITAL.

IN the following somewhat remarkable series of cases, all of them treated at the Prince Alfred Hospital, Sydney, death was due to a common cause—viz., inability of the respiratory centre to perform its functions, due in all probability to increase of intra-cranial pressure. Besides this common feature several of the cases developed clinical phenomena in themselves of considerable intrinsic interest. We shall give in each case a brief clinical sketch of the symptoms and an epitome of the pathological conditions found after death. These will be followed by brief remarks upon interesting or remarkable symptoms shown by individual cases; and, finally, we shall deal with those features common to them all.

CASE 1. *Interventricular hæmorrhage.*—The patient, a female aged fifty-four years, was admitted in a dazed condition, could answer questions but very slowly, and complained of pain in the occipital region. No paralysis or paresis was present. The temperature was normal. The heart and lungs were clear. Later in the day her condition improved, but about seven hours after admission she was suddenly seized with respiratory embarrassment, followed a few minutes later by total cessation of respiratory effort. At this time the heart was beating strongly and regularly. On practising artificial respiration the air way was found to be quite clear. As no effort at respiration was made artificial respiration was abandoned, and the heart ceased beating in about ten minutes.

Necropsy.—Blood-clot was found in the subdural space in the cerebellar fossa, continuous with a clot which distended the fourth ventricle and extended through the iter into the third ventricle.

CASE 2. *Basal meningitis; chronic internal hydrocephalus.*—The patient, a male aged twenty-seven years, complained of occipital and cervical pain shooting down to the shoulders and aggravated by moving the head. Five years previously he was said to have had a "sunstroke" and to have been "unconscious" for three weeks. Some months previously to admission he had repeated attacks of vomiting. During the last three months pain in the head and neck had appeared. The temperature on admission was 102° F., but fell to normal next day. The heart and lungs were normal, as was also the urinary system. There was tenderness as well as pain in the occipital region and part of the neck below it. There was no impairment of sensation and no paresis. The plantar reflexes were well marked, the patellar reflexes were exaggerated, and there was no ankle-clonus. Ten days after admission the patient became cyanosed and respiration ceased. After entire cessation both of costal and diaphragmatic efforts automatic movements of the lower jaw and alæ nasi persisted, and attempts at swallowing were made. Finally these movements also ceased. The pupils were regular, equal, and contracted, and the conjunctival reflex was present. As the heart continued to beat strongly it was deemed advisable to perform artificial respiration. The shoulders and neck were elevated, the head was thrown back, the tongue was drawn forward, and artificial respiration commenced. This was continued for an hour, strychnine and ether being meanwhile administered hypodermically. At the end of the hour slight attempts at breathing were made; these were continued and the patient recovered. Six days later he had a similar attack and recovered after artificial respiration. After several more such experiences he finally died eight days after the first attack.

Necropsy.—There were signs of both old and recent cervical and basal meningitis. The foramen of Magendie was occluded. There was hydrops of the fourth ventricle, iter, third ventricle, and both lateral ventricles.

CASE 3. *Cerebral hydatids.*—The patient, a male aged nineteen, had been operated on about three years before his present admission and a hydatid pressing on the motor area removed (Mr. Clubbe's case). Since leaving hospital he had enjoyed fairly good health, though being quite blind from optic atrophy following neuritis. He was readmitted with paralysis of the right arm of gradual onset. There was no vomiting. It was proposed to again open the skull, but on the morning of the projected operation his breathing suddenly became stertorous and finally stopped. Artificial respiration being carried on, his heart continued to beat for three-quarters of an hour.

Necropsy.—Four hydatid cysts were found at the posterior part of the left cerebral hemisphere. One was as large as an orange, the second about the size of a goose's egg, the third the size of a hen's egg, and the fourth had collapsed. The brain substance around was somewhat condensed. The largest cyst was bulging into the cavity of the left lateral ventricle.

CASE 4. *Malignant disease at the base of the skull.*—The patient, a female aged twenty-four, had had intermittent pains in the head for three years. The pain was described as commencing at the occiput and "shooting forward out of the right eye." Five months previously the sight in the right eye became so bad that she could not see to read on closing the left eye, and soon after this she noticed a difficulty in breathing through the right nostril. The nose was examined by a surgeon, who observed a mass at the back of the right nostril which he took to be a polypus and removed. Three weeks after the operation she had severe hæmorrhage, and this recurred some weeks later. Shortly after this she had another hæmorrhage, on account of which she was admitted to Prince Alfred Hospital. On admission at 2 P.M. the patient was found to be very anæmic; her pulse was rapid, but not very weak. She was very restless, throwing her arms about a good deal, and complained of thirst. The naso-pharynx was plugged, and a pint of normal saline solution was administered per rectum. At 10·30 P.M. the patient was very restless; the bleeding had ceased and the pulse had improved. She was given another saline enema, and also one-fifth of a grain of morphia hypodermically. At 12 midnight the patient's tongue fell back into the pharynx and she began to choke. On pulling forward the tongue and lowering the head she began to breathe again, but remained quite comatose and had no conjunctival reflex. The breathing, which was slow and stertorous, gradually became slower and finally ceased at 12.45. As the pulse was then good, artificial respiration was commenced and continued for two hours. For an hour and three-quarters the pulse continued fairly good and then gradually failed.

Necropsy.—There was a soft reddish tumour at the base of the skull pressing on the right temporo-sphenoidal lobe and displacing it to the extent of a space about as large as a hen's egg. The right crus was much flattened by pressure of the tumour. The latter had invaded and destroyed the sphenoidal and ethmoidal air cells on the right side and had invaded the upper part of the right nostril. The right side of the Gasserian ganglion and the optic nerve were involved in the growth.

CASE 5. *Basal meningitis, chronic internal hydrocephalus, syphilitic arteritis, and gumma of frontal lobe.*—The patient, a male aged thirty-seven years, had been ailing for two or three months with first giddiness and then headache. The eyesight had been gradually failing, so that he could not see to read. There was no numbness or anæsthesia. The patellar

Digitized by Google

reflexes were normal. The pupils reacted to light and accommodation. The tongue was dirty. There were diarrhœa and anorexia, but no vomiting. There was a slight history of alcohol and of syphilis contracted six years previously. About ten days after admission his pupils were observed to be unequal. A further examination of his eyes revealed the following facts. The pupils were unequal, the left circular diameter being 2 mm. and the right, which was vertically oval, about 4 × 3 mm. Both contracted well to near fixation, but were irresponsive to light. Vision of the right eye was = $\frac{6}{12}$, and that of the left = $\frac{6}{6}$. There was slight double optic neuritis. Three weeks after admission it was noticed that the patient's right arm was paretic. From this time onwards his condition went steadily from bad to worse, in spite of forty-five grains of iodide of potassium administered daily. There was marked mental deterioration—first, great emotionalism, and then increasing stupidity. Six weeks after admission his state was as follows. He had scarcely any intelligence and passed both urine and fæces involuntarily. There were paresis of the muscles of the right side of the face, including the orbicularis palpebrarum, marked exaggeration of both patellar reflexes, with patellar clonus and ankle-clonus on the right side. About seven weeks after his admission his respiration suddenly became slower and stopped. As his pulse was still good, artificial respiration was continued for about an hour and a half. Several times the artificial respiration was stopped until the radial pulse became almost imperceptible, then, on recommencing the respiration, the pulse regained its former strength. As after an hour and a half the patient made no attempt to breathe the efforts were abandoned.

Necropsy.—Endarteritis of branches of the basilar artery was found, also basal meningitis closing up the foramen of Magendie, and there was a gumma as large as a small hen's-egg in the left frontal lobe surrounded by an area of white softening.

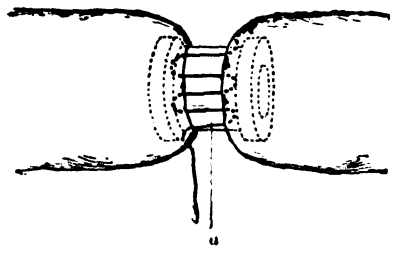
CASE 6. *Cerebellar tumour; internal hydrocephalus.*—The patient, a female aged ten years, had had nine months before admission some abdominal symptoms diagnosed as tuberculous peritonitis. On admission the symptoms pointed to caries of the lumbar spine. Six weeks previously she had pain in the head and back, with "convulsions"; twelve days after admission she had another attack of "convulsions," leaving pain in the head and back accompanied by strabismus. The pupils were dilated and equal, and there was no paresis. The girl regained her previous condition. Nine days later she had another "fit," when respiration ceased, the pulse remaining strong and regular. The heart continued to beat while artificial respiration was carried on for over two hours.

Necropsy.—A tuberculous mass about the size of a hen's egg, but irregular in shape, was found in the roof of the fourth ventricle, protruding into that cavity and distending it, and at the same time invading the right lobe of the cerebellum. The iter was greatly distended, and to a less extent the third and lateral ventricles. A large amount of clear cerebro-spinal fluid escaped when the brain was being removed, through rupture of the dilated stalk of the pineal body.

Remarks.—Case 2 presents several very interesting features; the symptoms, which resembled a good deal those of caries of the upper cervical vertebræ, were dependent upon a basal meningitis. Probably also the supposed sunstroke five years before was of a similar nature. The cause is difficult to divine. It will be noticed that the conjunctival reflex persisted after attempts at respiration had ceased—exactly the opposite to what is observed in poisoning by chloroform and similar drugs. It seems remarkable also that the accessory movements of respiration should have continued after the essential ones had ceased. Another point of interest is the contracted state of the pupils in a patient dying from asphyxia. Perhaps the strangest feature of the whole case is that natural respiration should have recommenced at all, seeing that the cause of its failure still persisted. Case 4 is in one respect the reverse of Case 2, for the conjunctival reflex was lost before the efforts at respiration ceased. Case 5 presents several points of interest. The steady progress of the disease in spite of large doses of iodide of potassium is contrary to the usual experience. The development of such marked mental symptoms in connexion with a lesion of the left frontal lobe is interesting. A very remarkable point is the development of the Argyll-Robertson pupil while the patient was under observation. Apart from locomotor ataxy and general paralysis the phenomenon must be exceedingly rare. The one feature common to all these cases is that death was in all probability due to the increase in intra-cranial pressure causing paralysis of the respiratory centre in the floor of the fourth ventricle. In four of the cases recovery, complete or partial, was theoretically possible if the immediate cause of death could have been removed. Hæmorrhage, syphilis, and localised tubercle may all be recovered from, while in a fourth case death was clearly caused by a mere blocking of the foramen of Magendie. These are not selected cases, but are simply taken as they occurred successively. The question obviously suggests itself as to whether anything surgical could be done in such desperate cases. If the pressure in the fourth ventricle could be relieved it seems to us that recovery might be possible. If the foramina which connect the ventricles of the brain with the subarachnoid space were patent, then opening of this space would be all that was necessary. If, on the other hand, these were blocked, as occurred in four of our cases, then two possibilities suggest themselves: one is to give temporary relief by tapping one of the lateral ventricles, and the other is to trephine the cerebellar fossa and make an attempt to rupture the roof of the fourth ventricle. No anæsthetic would be needed, but considerable difficulty might be experienced in attempting to operate on the back of the head whilst artificial respiration was being carried on, owing to the position of the patient. It is scarcely likely that an automatic apparatus such as is used in a physiological laboratory would be found in a hospital.

A NEW BOBBIN FOR INTESTINAL ANASTOMOSIS.

BY HERBERT WILLIAM ALLINGHAM, F.R.C.S. ENG.,
SURGEON TO THE GREAT NORTHERN HOSPITAL; ASSISTANT SURGEON TO ST. GEORGE'S HOSPITAL.



IT is with some hesitation that I venture to suggest a new bobbin for intestinal anastomosis, which appears to me to supply wants and to obviate faults, or rather disadvantages, noticeable in most of the other bobbins or buttons which have been designed. In my opinion some form of apparatus is necessary to unite hollow viscera one to the other. Now, a bobbin acts as a kind of splint while union is taking place, preventing any contraction or dilatation of the gut at the seat of union, and thus does away with any chance of leaking in the line of suturing. When no form of bobbin has been used, as in suturing by Mansel's or by Halsted's method, the seat of suturing has no support, and even a slight dilatation or contraction of the gut may easily allow some leak between the sutures to occur at the place of union. Again, rest and fixation favour union in the case of viscera, in the same way as with other parts of the body, and hence arises the necessity of a bobbin to secure that rest which is imperative for the sound joining of intestine to intestine, stomach to intestine, &c. It is thus seen that in intestinal anastomosis some plate, bobbin, or button is desirable, if not absolutely necessary.

Before describing my new appliance it may be allowable for me to point out some of the disadvantages in the plates, bobbins, or buttons which are the most frequently used in intestinal surgery. The bobbin designed by Mr. Mayo Robson appears to be the best, for it is made of decalcified bone, and as it is therefore absorbed there is no fear of its remaining for an indefinite time in the intestinal tract as a foreign body. The only disadvantage is that the flanges, or rather edges, at the ends of the bobbin are separated from one another by about three-fourths of an inch; hence, when viscera are being brought together, it is necessary to use some kind of suture running from one to the other, a process which takes some time to perform. (See Fig. 1, *a*.) Moreover, when the viscera have been brought together over the bobbin they can slip from one end of it to the other. At times, indeed, there is a fear of the bobbin slipping out from the seat of union, and this has actually occurred in one of my cases. Senn's plates appear to allow the edges of the incision in a viscus to fall together, and thus the communications between the viscera are too small later. This arises from the circumstance that while union is taking place there is nothing in the openings to keep them patent. It is obvious that this condition is rendered impossible by Mayo Robson's

Digitized by Google

bobbin or Murphy's button. With regard the latter there are several objections. It does not seem advisable that a hard metal button should be employed for anastomosis; for, in the first place, the button may be delayed in the intestine for a very long time, as in Lane's case, in which it did not come away even in 160 days. Again, when one considers the varying sizes of the ileo-cæcal valve it is readily conceivable that the button might be unable to pass the

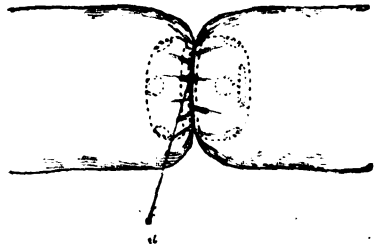


FIG. 1.

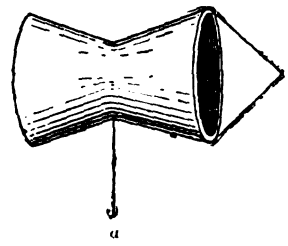
a

valve and might cause obstruction at that situation. In gastro-enterostomy the button might fall back into the stomach and then be unable to pass the pylorus or be vomited through the œsophagus. Further, it is not judicious to press intestines together at their seat of union by a button which, as far as I can see, can come away only by absorption or by sloughing of the pressed parts which have been brought together between its two pieces. (Fig. 2, *a*.) In no other way

FIG. 2.

a



can the button free itself from the intestine at the seat of union. No less than five cases have come to my knowledge in which sloughing with perforation took place at the seat of union, the patients dying from the consequent peritonitis. It is perfectly sound to hold that the intestines at the seat of union should be kept together by pressure, but this pressure must not be too great or too small. Still, it is desirable to devise some mode of maintaining this pressure which will not necessitate any absorption or sloughing in order to free the button when the parts have been sufficiently glued together.

It is to remedy the various disadvantages indicated above that I have designed my bobbin. Its principle rests in the fact that it consists of two cones with their apices coming together to form the centre. The tubes are of bone or ivory, the shape of two hollow truncated cones with their lesser ends together, having the appearance of small dice-boxes. These are carefully decalcified to within about three-sixteenths of the centre (*a*), leaving at the junction of the two cones a hard, unyielding portion upon which any pressure from the sutures is borne. The ends of the tubes are quite soft. There are several sizes, the most usual being—

Diameter of bore.	Diameter of end (outside).	Length.	Angle of cones.	Known as—
¼ inch.	⅜ inch.	1¼ inch.	150°	No. 1 size.
⅜ „	½ „	1½ „	140°	No. 2 „
½ „	⅝ „	1¾ „	140°	No. 3 „
⅝ „	¾ „	1¾ „	140°	No. 4 „

They can be made in any other sizes required, but the above four sizes can always be had without delay from Messrs. Krohne and Sesemann, Duke-street, Manchester-square, W. This appliance is exceedingly simple and appears to serve all the purposes required of a bobbin or button, for it keeps the parts at absolute rest; can be absorbed, as it is made of decalcified bone; and can be liberated without any absorption or sloughing of the parts it unites. Moreover, from its shape it cannot, until the decalcified bone is absorbed, slip away from the seat of union, and when the sutures in each piece of intestine are tied the parts to be joined must be brought together, and yet no excessive pressure is exerted on the edges which it is desired to connect. As the bobbin may be used in various operations, it has been made in different sizes. Those for gall-bladder cases are one-fourth of an inch wide at the narrowest point—viz., the centre (Fig. 3, *a*); in

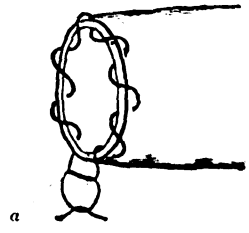


FIG. 3.

a

those for small-intestine cases, seeing that the intestinal contents are liquid, the width at the narrowest point need not be more than one-half or three-eighths of an inch. Much larger ones are required for large-intestine cases, as the intestinal contents are solid or semi-solid—viz., three-fourths of an inch. Though the bobbin may be employed to unite intestine to stomach, gall-bladder to intestine, and indeed in any form of anastomosis, its use may be most conveniently explained by presuming that two pieces of intestine are to be

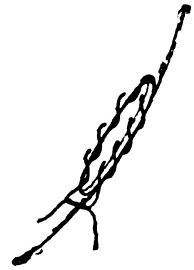

FIG. 4.

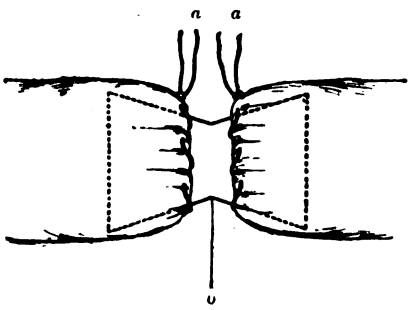
a

united end to end. Into or round each piece of intestine a fairly stout continuous silk suture is passed, which should include in each stitch the peritoneum, the muscular coat, and the mucous coat (Figs. 4 and 5). Then one end of the bobbin is inserted into one piece, and the suture is pulled tight by a knot twice threaded, so that it will not slip (Fig. 4, *a*), but the final tie is not made until the other end of the bobbin has been inserted into the other piece of intestine. After this, one of the sutures is tightened up to its utmost; this brings the part down to the centre of the

FIG. 5.



bobbin, for, as the bobbin consists of two cones with their apices pointing to its centre, the tighter the suture is drawn (Fig. 6, *a*) the more completely must it draw the intestine to the apex of the cone (Fig. 6, *b*) which has been inserted into it. A similar tying of the other suture brings the other piece of intestine down to the apex of its cone (Fig. 7, *a*). Thus, from the shape of the bobbin, the parts to be united are brought into exact apposition and at the same time are pressed together. A few Lembert's

Digitized by Google

sutures may then be inserted at various points, or a continuous Lembert's suture may be used all round if that be thought necessary. It is wise to scarify the peritoneum of the intestines with a needle for about half an inch round the seat of union. This scarifying promotes the exudation of lymph, which acts as a callus (just as in a fracture of bones) round the ends to be united. Especially should this be done if no Lembert's sutures have been employed. The intestines when united cannot move in either direction, for the sutures, which are tied up tightly at the narrowest part of their

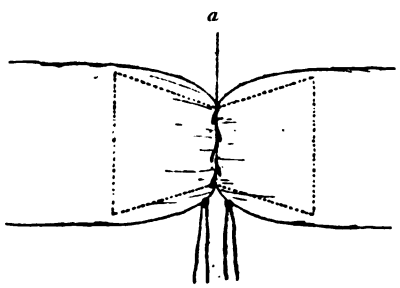


FIG. 6.

respective cones, naturally cannot slip up to any broader portion; moreover, the bobbin itself cannot possibly alter its position either upwards or downwards.

Murphy's button and Mayo Robson's button are sometimes blocked by solid fæces which have to travel through them for some distance (about an inch). Now, since my bobbin is shaped like an hour-glass, there is an extremely small surface to obstruct the passage of solid matter; this may be represented as being merely the extent of a line—i.e., at the meeting of the apices of the cones. This is quickly passed, and then the cones grow wide once more.

FIG. 7.

Simplicity is, I think, the characteristic of the bobbin. No complicated suturing is required, nothing being needed except the continuous sutures—one round one end of the divided intestine, and the other round the other end—or, in a similar manner, round the incisions, one in one viscus and the other in the other. Hence it can be applied very rapidly. Further, it cannot slip, and in consequence of its shape the parts to be joined are brought closely together. Lastly, it is absorbed in time and therefore cannot act as a foreign body. I have experimented many times with the bobbin on the dead body and find it is most easy of application, and the operation rapidly carried out. At present I have had only one opportunity of using it upon the living subject, and in this case with excellent results.

Grosvenor-street, W.

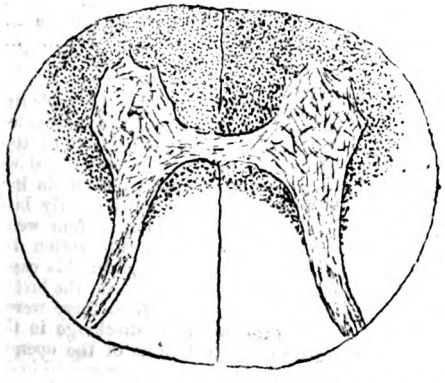
HEAVY FINES FOR ADULTERATING MILK.—At Southwark Police-court, on Tuesday, Aug. 27th, David Jenkins, of Guy-street, Bermondsey, and Joseph William Bramley, of Weston-street, Bermondsey, were summoned under the Sale of Food and Drugs Act, at the instance of Mr. Henry Thomas, inspector to the Bermondsey Vestry, for having unlawfully sold milk adulterated with added water to the extent of 19 and 18 per cent. respectively. The cases having been proved, Mr. Fenwick fined Jenkins, against whom there were previous convictions, £20 and 12*s.* 6*d.* costs, and Bramley £3 and 12*s.* 6*d.* costs.

SPINAL SOFTENING LIMITED TO THE PARTS SUPPLIED BY THE POSTERIOR ARTERIAL SYSTEM OF THE CORD.

BY R. T. WILLIAMSON, M.D. LOND., M.R.C.P.,
MEDICAL REGISTRAR, MANCHESTER ROYAL INFIRMARY, AND ASSISTANT IN MEDICINE, OWENS COLLEGE.

THE spinal cord is supplied with blood at its anterior part chiefly by a long narrow artery, the anterior spinal, and at the posterior parts by two long narrow vessels, the posterior spinal arteries. These arteries are reinforced by numerous small arterial twigs coming from the intercostal lumbar and sacral arteries, which enter the spinal canal by the intervertebral foramina and run along the anterior and posterior nerve roots. A number of small arteries, derived from the vessels on the surface, enter the substance of the spinal cord: the largest of these are the anterior median arteries, which penetrate the anterior median fissure. The exact distribution of these branches within the cord is described in most anatomical text-books. Now the blood supply of the cord may be divided broadly into the anterior and posterior arterial systems; and a transverse section of the cord may be divided roughly into two districts or areas—one supplied by small arteries coming from the anterior arterial system and the other by arteries from the posterior system.[1] The blood supply to the interior of the cord by the anterior spinal arteries is more important than that by the posterior arteries. The distribution of the lesions in a number of spinal diseases is related to the vascular supply, as I have pointed out elsewhere.[2] A spinal cord which I have recently examined furnishes a beautiful example of the localisation of the lesion to the part supplied by the posterior arterial system. During life the patient was under the care of Dr. Graham Steell, to whose kindness I am indebted for the opportunity of making the pathological examination.

A man fifty years of age, suffering from paraplegia, was admitted as an in-patient to the Manchester Royal Infirmary on Aug. 29th, 1894. His previous health had been good until three weeks before admission, when he suddenly lost the use of his left leg immediately before getting into bed in the evening. He had just passed urine and was pulling off his stockings when he found that he was unable to raise the left leg. He thought that the right leg became paralysed soon afterwards. There was no pain in the back or limbs at the onset, but the legs felt numbed. He stated, however, that he could feel when anything touched his legs. Very soon after the onset of the paralysis the legs became painful, especially the left, and there had been dull, aching pain, with occasional sharp, shooting pains, in the legs ever since. Retention of urine had been present from the onset and a catheter had been passed daily. The legs had remained completely paralysed from the commencement. The arms had not been affected, and there had been no pain in the back. There is no history of syphilis or gonorrhœa or rheumatism. With the exception of two attacks of pleurisy (one eight years and the other twenty years before admission) the previous health has been good, until one month before the onset of the paralysis. At that date he began to feel languid, but was able to attend to his work quite well.



On admission to the infirmary the patient was somewhat wasted. Both legs were completely paralysed, and the feet and toes were "dropped." The legs were flaccid; the knee-jerks were present; there was no ankle-clonus; and the plantar reflex was present on the left side, but was not obtained on the right. The abdominal, epigastric, and cremasteric reflexes were not obtained. A light touch with the head of a pin was not felt on the right leg; a pin prick also was not felt. On the left leg both the point and head of a pin were felt and localised. On the abdomen the head and the point of a pin were not felt on the lower part—up to a point midway between the pubes and umbilicus; above this level both were felt distinctly. There was no zone of hyperæsthesia just above the anæsthesia. The patient could

Digitized by Google

distinguish hot and cold test tubes on both legs. The bladder was distended; there was retention of urine, with dribbling. There was also incontinence of fæces. There was no pain in the back, but the patient had considerable pain in the legs, especially when moved. The first lumbar vertebral spine was very slightly prominent, but there was no tenderness on percussion at this region. The arms were unaffected. There was no paralysis of the facial, ocular, of tongue muscles. When the edge of a silver coin was drawn firmly over the skin in any part of the trunk or limbs a peculiar bluish-black mark remained, and the patient's initials could be written quite easily on the chest and abdomen. The pulse was 105 and intermittent; one beat was missed in about every 10. The tension was normal, and the artery not atheromatous. There was a short systolic murmur limited to the apex, but the cardiac dulness was normal. Physical examination of the lungs and abdominal organs revealed nothing abnormal. The urine was dark in colour, ammoniacal, and very fœtid, the specific gravity being 1017. It contained a small amount of albumin and a deposit of triple phosphates, a few pus cells, mucus, and a few red corpuscles. By the end of October the anæsthesia had increased, and both legs were equally affected. The anæsthesia was most marked on the outer side of the leg, but, owing to the patient's dull mental condition, it was not possible to map it out accurately. At a later date the results of examination of the cutaneous sensibility were quite unreliable. Soon after admission a sacral bedsore developed and the general condition of the patient became gradually worse. He complained most of pain in the legs, which was very severe when the limbs were moved. The doubtful prominence of the first lumbar spine did not increase, and spinal tenderness did not develop. The reflexes remained the same as on admission, but the bladder symptoms and the bedsores became much worse, and the patient died on Jan. 2nd, 1895.

Post-mortem examination.—The body was found to be greatly emaciated. There was an extensive sacral bedsore. The pericardium was normal. Fibrous pleuritic adhesion was present on the left side. There was slight thickening of the cusps of the mitral valve. Tuberculous nodules were scattered throughout the right lung. The stomach, intestines, liver, kidneys, and spleen presented no important changes. The bladder showed well-marked signs of cystitis. The spinal column presented no signs of angular curvature or caries. There was no evidence of tumour growth in the vertebræ. The spinal cord appeared to be normal to the naked eye. On section the grey matter in the lumbar and lower dural regions was seen to be congested. The spinal dura mater was adherent in the lower dorsal and lumbar regions to the posterior surfaces of the vertebræ; otherwise the spinal meninges were normal. After hardening in Müller's fluid, the cord, on transverse section, presented to the naked eye well-marked degeneration in the posterior and lateral columns of the lower dorsal region for about two inches. These columns were much lighter in colour than the rest of the transverse section. Above and below the region just mentioned the usual secondary degeneration could be detected. The whole of the lower two inches of the dorsal region of the cord was cut into small pieces, which were embedded in celloidin, and sections made. Every third or fourth section was mounted and examined microscopically. Practically, therefore, the whole of the cord at the seat of the lesion was examined microscopically. The sections were stained according to the methods of Weigert and Pal, and also with logwood and eosin and with aniline blue black. The figure represents the appearance of a transverse section (stained according to Weigert's method) through the lowest dorsal region, at the part where the lesion was most intense. The black dots represent healthy nerve fibres in the white matter, the fine lines represent the small nerve fibres in the grey matter, and the blank part corresponds to the area of degeneration in which nerve fibres are very scanty or altogether absent. (In the sections stained according to Weigert's method this blank area is light brown.) In the figure nerve fibres are represented (by fine black lines) in the posterior horns of grey matter, but in a good number of sections the posterior horns were completely degenerated, and their black-stained nerve fibres absent. The degeneration affected the posterior columns, median and external, with the exception of a narrow zone, close to the grey matter of the commissure and to the neck of the posterior horn; it affected the region of the lateral pyramidal, the direct cerebellar, and the antero-lateral ascending tracts, and also extended a little farther forwards on the surface of the cord. Under a high power the part where the changes were most intense—i.e., the whole of the posterior columns, with the exception of the narrow zone adjacent to the grey commissure and to the neck of the posterior horn—was seen to be densely infiltrated with round cells—large mononuclear cells, compound fat granular cells, and leucocytes. The nerve fibres were absent, and only a few irregular fibres of neurogliar tissue were seen amongst the cell infiltration. The microscopical appearance was that of spinal softening. The bloodvessels were dilated and their walls studded with nuclei, but the vascular changes were certainly not so marked as is usually the case in so-called myelitis. A large portion of the degenerated area in the lateral columns presented similar appearances of softening (cell infiltration, &c.). In some of the sections these changes had extended into and destroyed the posterior horns of grey matter. In other sections at this level of the cord the changes were more chronic than those just described, but involved the same area in the posterior and lateral parts of the cord. The nerve fibres were scanty, or absent altogether; the neuroglia was greatly increased and presented round or oval spaces, from which the nerve fibres had disappeared; and the changes then resembled those met with in secondary degeneration or sclerosis. The grey matter of the anterior horns and the intermediate grey matter appeared to be quite normal. The ganglion cells and fine nerve fibres were brought out quite distinctly—by different methods of staining. The whole of the anterior white matter was normal. In some sections small ante-mortem blood-clots were found in the veins on the posterior surface of the cord, and in a few sections they were also found in the veins near the anterior median fissure. The clots in all cases consisted of numerous leucocytes with a few red corpuscles, and were always separated by a small space from the vessel walls. No clots were found in the spinal or meningeal arteries. The walls of the bloodvessels appeared to be normal except at the seat of the changes in the posterior and lateral columns. Above the seat of the lesion just described there were the usual ascending changes in the posterior columns (secondary sclerosis), and below there was the usual descending sclerosis in the lateral pyramidal tracts. Only in the lower two inches of the dorsal region of the cord were the above-described suffering and degeneration found in the posterior and lateral columns.

Section of spinal cord (Weigert's stain). Black dots and lines=healthy nerve fibres; the blank area=softening and degeneration.

Remarks.—The changes at the seat of the lesion I have described as spinal softening rather than myelitis, because the former term does not necessarily imply an inflammatory origin. The case is of interest on account of the localisation of the changes just to that part of the cord which is supplied by the posterior arterial system. If we compare the above figure (showing the distribution of the lesion) with that given by Marie (Diseases of the Spinal Cord) to show the distribution of the anterior and posterior arteries of the cord, we shall find that the blank area of degeneration corresponds almost exactly with the part of the cord which Marie maps out as that supplied by the posterior arterial system. The very sudden onset of the symptoms is also very suggestive that the lesion was of vascular origin.

THE RESULTS OF OPERATIONS FOR CANCER OF THE BREAST.

BY THOMAS JONES, B.S., F.R.C.S.,
SURGEON TO THE MANCHESTER ROYAL INFIRMARY AND PROFESSOR OF SURGERY IN THE OWENS COLLEGE;
AND
JOHN E. PLATT, M.S., F.R.C.S.,
RESIDENT SURGICAL OFFICER, MANCHESTER ROYAL INFIRMARY.

BEFORE a correct estimate of the true value of any operation can be formed it is necessary to consider the ultimate results with which it is attended. It is not enough to know what the immediate risks of its performance may be; we should also find out what are likely to be its remote effects. It seems to us that hardly sufficient stress is laid on this matter, and that we are too apt to be satisfied if the immediate results come up to expectation. These remarks apply with peculiar force to the operations performed in cases of malignant disease, and it is very possible that if we were more thoroughly acquainted with the late results of operation in such cases we might pause before we recommended our patients to submit to them. The accompanying table deals with all the cases of carcinoma of the breast which were operated upon by Mr. Jones at the Manchester Royal Infirmary during a period of ten years (1883 to 1892 inclusive). It gives particulars of the cases when they first came under observation, and also records the results of our inquiry into their after-history. This inquiry has been a work of considerable difficulty and labour, as anyone who has been engaged in similar work will know; the patients have been widely scattered, and difficulties have arisen from changes of residence and from many other causes. The table includes 55 cases, of which more or less information of the after-progress was obtained in 52 cases. In spite, however, of all our efforts we were unable to learn anything more about the remaining 3 cases. In the present paper we propose to deal in the first place with certain points which are illustrated by the histories given and the symptoms presented by the patients at the time they first came under observation; secondly, with the results of our inquiry into the after-progress of the cases; and, thirdly, with certain conclusions which we have deduced from a careful study of the facts now before us.

From an analysis of the cases we obtain the following particulars with regard to sex, age, family history, &c. All the 55 patients were women; no examples of cancer of the male breast have come under observation during the period under consideration. Seven patients were between the ages of thirty and forty, 30 between forty and fifty, 12 between fifty and sixty, 5 between sixty and seventy, and 1 was over seventy years of age. The great majority—more than half the cases—were thus between forty and fifty, the period of life at which cancer generally is most frequently met with. In 23 of the 55 cases the right breast was affected by the disease, in 29 the left breast, whilst in the remaining 3 cases the notes give no information upon this point. The nature of the growth was in all cases scirrhous; 2 were examples of atrophic scirrhus. A family history of malignant disease was obtained in 7 cases only (12·7 per cent.). In our table we have an account of a mother and daughter and the mother's sister suffering from cancer. The mother's sister (No. 3 in the list) is still living and free from recurrence, although the operation took place eleven years and three months ago. A history of previous breast troubles was given in 11 cases (20 per cent.). There had been abscess in 5, sore nipple in 3, sanguineous discharge from the nipple in 1, "broken breast" after confinement (probably abscess) in 1, and severe pain in the breast during suckling in 1. From this it appears that cancer is especially liable to occur in breasts which have been previously affected by abscess or other disease. A history of injury to the breast was obtained in 8 of the 55 cases. As to the duration of the disease before the patients came under observation, so far as we could learn the disease had in 11 cases been in existence for less than three months before operation, in 9 it had existed from three to six months, in 6 from six to nine months, in 15 from nine to twelve months, and in 9 from one to two years, whilst in the remaining 5 cases the duration is doubtful. It must not be forgotten, moreover, that the onset of cancer of the breast is usually insidious and that the disease has made very considerable progress before it is noticed by the patient. Frequently she discovers a tumour of large size whose presence has hitherto remained unsuspected. The great length of time which often elapses between the discovery of the tumour and the time the patient seeks advice is worthy of notice, since it allows the disease to become much more extensive and thus necessitates a more formidable operation and greatly increases the chances of recurrence. In 32 of the 55 cases the first symptom noticed by the patient was the presence of a "lump" in the breast, in 8 pain was the first symptom, and in 7 retraction of the nipple. In 1 case the patient noticed that the axillary glands were enlarged before she observed any swelling in the breast, and in 2 failure of the general health led to the discovery of the local disease. With regard to the state of the skin over the breast, in 34 of the 55 cases the skin was adherent to the tumour, in 10 of these being distinctly infiltrated by the new growth, and in 1 ulcerated. Several other cases showed dimpling when the overlying skin was pinched up between the fingers. The nipple was retracted in 37 cases, unaltered in 14, whilst its condition was not recorded in 4. In 2 patients it was ulcerated and in 2 the disease was preceded by inveterate eczema (Paget's disease). The axillary lymph glands were distinctly enlarged in 47 cases, apparently uninvolved in 7, and the glands along the pectoral muscle were alone involved in 1. It is very significant (and this has an important bearing on a point of practice which we wish to emphasise) that in 7, or nearly one-eighth, of our cases no enlargement of the axillary glands could be felt before operation, and yet enlarged glands were discovered when the axilla was opened. This proves that it is never safe to conclude that no enlargement of the axillary glands exists unless the examination of the space is conducted through the wound. This is especially true of those cases in which the axilla contains an abundance of fat, under which circumstances small shotty glands may, and very often will, elude detection. The supra-clavicular glands, in addition to those in the axilla, were slightly enlarged in 4 cases, and in these a speedy recurrence of the disease took place after operation; indeed, the operations in these cases were incomplete, as all the infected glands could not be removed. It would have been better if these 4 cases had been left untouched; they were manifestly unfit for operation.

Results of operation.—The ultimate results, so far as we have been able to learn, are as follows:—

Deaths soon after operation	2
Patients who have died without recurrence ...	2
,, ,, ,, from recurrence	34
,, now living with recurrence	8
,, ,, and free from recurrence ...	6
No further information obtainable...	3
	55

Of the 2 deaths which occurred whilst the patients were in hospital 1 (Case 42) took place eight weeks after operation from chronic bronchitis and dilatation of the heart. We think that this death ought not to be put down to the operation, since the patient recovered from its immediate effects and progressed favourably until shortly before her death. The other patient (Case 1) died four weeks after removal of the breast from septic absorption from the granulating surface on the chest wall. In this case it was necessary to sacrifice much of the skin over the breast, and a large raw surface was left; at the time there were several extensive burns with profuse septic discharge in the same ward. With regard to the technique of the operation the axilla was opened and infiltrated glands removed in 47 of the 55 cases, and it was not opened in 7. Unfortunately, the notes of the remaining case are very imperfect and do not give any information upon this point. In one case the affected glands so completely surrounded the axillary vein that a portion of the vessel had to be sacrificed, yet no inconvenience beyond a temporary œdema of the arm was experienced by the patient. In 4 cases only was it deemed necessary to remove a portion of the pectoralis major owing to the extension of the growth to the muscle. In 1 case (No. 37) the tumour, which was situated near the axillary border of the mamma, was excised with some adjacent tissue without taking away the entire breast. This is a method of operating strongly to be deprecated; it was followed by speedy recurrence of the disease which necessitated a second

operation, and the patient died seven months later. Our rule is to remove the entire breast, to dissect off the pectoral fascia, to remove portions of the muscle if necessary, to examine the axilla through the wound, and if the glands be infected to clear it out completely, the breast and the glands, along with the intermediate lymphatic tract, being removed together in one piece. The assertion is frequently made that the immediate risks to life are greatly increased by opening the axilla at the time of operation. We contend, however, that the clearing of this space need add little, if any, to the risks, provided the proceeding be conducted with due care, and we would again point out that in 47 of our 55 cases the axilla was freely laid open and its contents completely removed, and yet there was only 1 death. In some of the cases the dissection required in order to excise the glands was most extensive, the axillary vein being frequently exposed for some two inches of its length. We hold, therefore, that no operation for removal of cancer of the breast is complete unless the axilla is carefully examined through the wound. If the glands be enlarged, be it ever so slightly, their removal is imperative. To leave them is to court defeat, as early recurrence in this situation must be expected. The only possible objection to the universal adoption of the rule of examining the axilla through the wound would arise from the additional risk involved, and the contention that the risk is greatly increased by this procedure falls to the ground in view of the results obtained. There is one practical point in connexion with this part of the subject to which we wish to invite attention. It is this: great watchfulness is required on the part of the anæsthetist whilst the axilla is being cleared out; the amount of shock is sometimes considerable, and it is well not to push the anæsthesia too far at this stage. We have been led to dwell at some length on the mode of dealing with the axilla because one sometimes sees cases in which the mammary gland has been successfully removed, but the axilla left untouched or only imperfectly dealt with; the disease has speedily declared itself in the latter situation and has advanced with alarming rapidity, thus bringing the operation into disrepute.

Of the patients who recovered from the operation 2 have since died from other diseases without recurrence of the cancer, one (Case 27) three months after her discharge from excessive drinking, and the other (Case 43) after eight and a half months from bronchitis. Recurrence, including the 4 patients in whom the operation was incomplete, took place in 42 cases, of which 34 have since died and 8 are alive. The average duration of life after operation in the 34 cases was nineteen and a half months; it was under six months in 5, from six to twelve months in 10, one to two years in 9, two to three years in 2, three to four years in 6, and four to five years in 2. Of the 8 cases now living with recurrence the average time since operation is four years; the longest period is eleven years

Digitized by Google

and six months and the shortest two years. The date of recurrence after the removal of the breast was doubtful in 8 cases, within three months in 8, three to six months in 7, six to twelve months in 1, one to two years in 8, two to three years in 3, three to four years in 1, four to five years in 1, and after ten years in 1. The recurrent growth was situated in the axilla without recurrence in the cicatrix in 9 cases, it affected the cicatrix on the chest wall or its immediate vicinity in 19, and the internal organs without local reccurrence in 4 (lungs 2, uterus 1, and subperitoneal glands 1). The opposite breast became affected by carcinoma in a late stage of the disease in 4 of the 38 cases. Operations for the removal of recurrent growths were undertaken in 11, or just 20 per cent. of the total number of cases; of these, three had two subsequent operations. The rule with regard to recurrent growths should be to remove them whenever practicable and as soon as possible after they are discovered. The remaining 6 patients are living and show no signs of return of the growth, the time since operation being eleven years, and three months in two instances, eight years and four months in two others, seven years in a fifth, and six years in the sixth. Leaving out of consideration those patients who died soon after the operation, those who have since died from independent diseases, and those who cannot be traced, 6 cases out of 48 have no recurrence after periods varying from five to eleven years. If we adopt Volkmann's rule that if a patient is free from recurrence three years after the removal of the growth she is to be considered cured, we can claim that 12·5 per cent. of our cases were cured by operation. This rule, however, is not always correct, for recurrence sometimes takes place at a very late period; one of our cases had recurrence after ten years.

From a careful consideration of the foregoing facts we have drawn the following conclusions:—1. Cancer of the breast, although a formidable disease, is amenable to treatment by operation, and the proportion of cures so obtained may confidently be put down at 12 per cent. 2. Non-success after operation is very frequently due to the extensive character of the disease when it first comes under observation; probably if relief were sought earlier a much larger proportion of cures would be obtained. 3. Moderate enlargement of the axillary glands is no bar to operation or to a successful issue provided they are systematically and carefully removed and the axillary space thoroughly cleared. 4. It is well-nigh impossible to discover trifling enlargement of the axillary glands by an examination through the unbroken skin. 5. No operation for removal of cancer of the breast can be considered complete unless the axilla be examined through the wound, the additional risks of such a procedure being very slight. 6. The large number of cases in which recurrence occurs locally points to the necessity of very free removal of the disease; all doubtful skin must be taken away and great care must be exercised not to leave any outlying portions of breast tissue. 7. Operation is contra-indicated when the whole of the growth cannot be removed or when the supra-clavicular glands are enlarged. The only condition which might render an operation justifiable under such circumstances would be the presence of a foul cancerous ulcer, the removal of which is desirable on account of the great inconvenience which it occasions.

Manchester.

STATUS EPILEPTICUS; REMARKABLE NUMBER OF FITS; RECOVERY.

BY J. W. ALEXANDER, M.R.C.P. EDIN.,
LATE ASSISTANT MEDICAL OFFICER, LANCASHIRE COUNTY ASYLUM, RAINHILL.

THE following case of epilepsy, in which the patient recovered after having had an extraordinary number of convulsions, may be considered of interest. It occurred in a woman twenty-six years of age, who was admitted to Rainhill Asylum on Jan. 4th, 1890, suffering from mania with epilepsy. From the date of her admission till the end of December, 1894, she had on an average four fits per month; one to two days intervened, as a rule, between each, and at no time were more than five fits recorded in twenty-four hours. After each group of fits she became excited, the excitement frequently assuming the form of post-epileptic mania of a violent type. Bromide of potassium was taken by the patient in thirty-grain doses twice daily from the middle of May, 1891, till the middle of December, 1894. The series of convulsions which forms the subject of this communication began on Jan. 2nd of this year, a fortnight after the bromide of potassium was discontinued, and ended twenty-one days later. The aggregate number of fits recorded during these twenty-one days amounted to 3245, the daily total reading as follows:—

Jan. 2nd	... ...	16	Jan. 9th	... ...	159	Jan. 16th	... ...	98
,, 3rd	... ...	38	,, 10th	... ...	51	,, 17th	... ...	123
,, 4th	... ...	280	,, 11th	... ...	112	,, 18th	... ...	135
,, 5th	... ...	330	,, 12th	... ...	98	,, 19th	... ...	238
,, 6th	... ...	285	,, 13th	... ...	165	,, 20th	... ...	168
,, 7th	... ...	211	,, 14th	... ...	151	,, 21st	... ...	87
,, 8th	... ...	321	,, 15th	... ...	89	,, 22nd	... ...	5

The convulsions were almost entirely confined to the right side of the body, beginning in the arm and spreading rapidly to the head, face, and leg. The arm was flexed, the leg drawn up, and the head and eyes rotated to the right; occasionally the left leg was involved, and more rarely the left arm also. During the paroxysm urine was passed, but not fæces, nor was the tongue bitten. Each fit was a distinct entity, well marked and severe, but of short duration, generally lasting from about thirty to forty seconds, and separated from that immediately preceding and succeeding it by a period of semi or complete consciousness. There can be little doubt that the patient's recovery may be attributed to the fact that these periods existed and were taken advantage of to give her a sufficiency of nourishment. As to treatment, a brisk purge was administered at the outset, and 111 grains of chloral hydrate were given in the first twenty-four hours, followed during the second twenty-four hours by 105 grains of the same drug. Afterwards ten grains of bromide of potassium and ten grains of chloral hydrate were given every three hours till Jan. 17th, when the amount of each drug was increased to thirty grains every four hours at first, and less frequently as the fits decreased in number and severity. After the final cessation of the convulsions the right arm and leg remained completely paralysed for a fortnight; then the paralysis gradually passed off. At this time, the patient's mental activity having returned, an examination into the state of her nervous system was made. She complained of great pain in the right shoulder, which was purely due to passive or active movement; there was no hyperæsthesia; sensibility to pain and touch remained unimpaired; the motor speech mechanism was unaffected; ophthalmoscopic examination revealed no morbid change; there was slight wasting of the right arm and leg, and the tendon reflexes were brisk, that of the right patella more so than the left. Concerning the further course of the illness, the paralysis has now (April, 1895) completely disappeared, some slight stiffness of the shoulder alone remains, and no more fits have been recorded.

I am indebted to Dr. Wiglesworth, the medical superintendent, for permission to publish the case, and to Dr. Milne, who was acting as locum-tenens at the beginning of the patient's illness, for the earlier notes.

Armley, Leeds.

CIRRHOSIS OF THE LIVER.

BY FREDERICK J. SMITH, M.D. OXON., F.R.C.P. ENG.,
ASSISTANT PHYSICIAN AND SENIOR PATHOLOGIST TO THE LONDON HOSPITAL.

IN THE LANCET of Jan. 5th there is published a case by Dr. H. B. Donkin which is termed malignant jaundice or acute yellow atrophy. I quite agree with Dr. Donkin that the case is rare and interesting enough to be worthy of publication, but I wish to ask, Was the diagnosis correct? My impression, from a careful study of the report, is that it was a case of the disease which I believe the late Professor Charcot first definitely described—viz., hypertrophic cirrhosis. Before I give the actual reason in my mind for my opinion—viz., an analogous case with microscopical post-mortem examination—I would like to say something about the features of hepatic cirrhosis in general, if it be only to correct what I find is a widespread erroneous view of the condition taken by students. For clinical purposes cirrhosis may be classified as follows: (1) irregular local cirrhosis due to scarring from healed abscesses, gummata,

Digitized by Google

hydatids, &c.—in fact, any local disease or injury which has healed by scar; and (2) general cirrhosis (which may, however, in certain cases implicate only a lobe or less), of which the forms are (*a*) congenital syphilitic, (*b*) by contraction of the capsule, (*c*) alcoholic or portal, and (*d*) hypertrophic, biliary, or non-alcoholic. I do not propose to enter into any discussion on irregular cirrhosis or on Groups *a* and *b* of the general class, but I do wish to express an opinion on some points in the features of Groups *c* and *d*.

With regard to Group *c* I accept the generally received opinion that the clinical symptoms are produced by—or, in other words, that the pathology of the condition is—first, the appearance in the portal canal, and its smaller divisions, of numerous small round nucleated cells; secondly, the formation from these cells of fibrous tissue; and, lastly, the contraction of this fibrous tissue with consequent pressure effects. Such being the pathology, it is obvious that process No. 1 must *tend* to increase the size of the liver, while process No. 3 must tend to diminish it. If this be granted, then it must follow that the size of a cirrhotic liver depends upon the relative activity of processes Nos. 1 and 3. This leads me to the error mentioned above—viz., that students always say that a cirrhotic liver is large in the early stages, but subsequently becomes small. That such may be the tendency of the pathological process I am not prepared to deny, but I feel very confident that clinically the small cirrhotic liver is the exception and not the rule. While medical registrar to the London Hospital I very carefully noted the condition of the organ as regards size in all cases diagnosed by the physicians as "cirrhosis of the liver," and in fully two-thirds of the cases the lower border was noted as being palpable below the ribs, often as low as the umbilicus. My experience as pathologist also points in the same direction. I very seldom see a small cirrhotic liver, but frequently enough one as large as or larger than usual; in fact, the most typical example of the condition I ever saw (and of which I have a microscopical slide) was a liver which weighed ninety-six ounces. Leaving now alcoholic cirrhosis for a moment, I pass on to say a few words about hypertrophic cirrhosis, the pathology of which is perhaps best given by its synonyms hypertrophic, non-alcoholic, biliary, and intralobular. The existence of such a disease I am prepared to admit, partly on authority (Charcot and others), and partly on experience of one case reported to me by Mr. J. A. Jones of Aberavon, who kindly sent me for examination a portion of the liver and spleen. A full report of the case appeared in the Transactions of the Pathological Society of London for 1890. Microscopically, the condition was precisely that described by authority—viz., cells and cirrhosis actually invading the individual acini. This disease I believe to be exceedingly rare, usually occurring in quite young subjects and presenting typically a large liver and intense jaundice with nervous symptoms prominent—in fact, just the picture Dr. Donkin draws of his case; this constitutes my reason for asking him if his case could have been of this nature.

My remarks are intended to be of a clinical character, and it is a clinical point on which I wish to insist for the sake of clearness—viz., that when we meet with a case presenting the features of alcoholic cirrhosis (i.e., ascites &c., with but little jaundice), and the liver happens to be enlarged (as is most usually the case), we should use the term "cirrhosis with enlargement," reserving the term "hypertrophic cirrhosis" for those rare cases in very young subjects in which intense jaundice, nervous symptoms, and enlarged liver are the prominent features.

Christopher-street, E.C.

ENTERIC FEVER: A THEORY OF EVOLUTION.

BY W. L. CHESTER, M.B. DUBL.,
SURGEON-MAJOR, ARMY MEDICAL SERVICE.

THE recognition of this disease dates from about the middle of the present century. For convenience I propose to term the time preceding its recognition the "prehistoric period," and the latter times the "historic period" of the disease. I will first propound the following postulates: (1) that enteric fever existed during the prehistoric period; (2) that during the prehistoric period, the days when sanitation as now understood was unknown, the typhoid germ was everywhere abundant, and that the disease attacked all susceptible individuals during their infancy; (3) that in infancy the disease readily escapes recognition; and (4) that since the historic period—the days of sanitation—infants commenced to escape the infection, and then for the first time it became a disease of adolescence, and thus became recognisable by the physicians of the day. Whether the specific or the pathogenic theory is the correct one, it is equally difficult to suppose that a disease, avowedly depending on want of sanitation, should not have existed in the days when sanitation practically did not exist. How does it happen, then, that the older observers failed to recognise it? A common fever, with such well-marked and distinctive clinical and pathological features, could not well have escaped observation or be confounded with other disease by at least some of the clever and observant physicians of the day, and yet while the details of other diseases are recorded with considerable accuracy and skill, enteric fever alone, of all the general diseases, escapes notice.

The explanation now advanced is that during the prehistoric period, the days when there were no public water supplies, but each household depended on its own well, pump, or river, when waterclosets, sinks, or sewers, if they existed, were untrapped, when filth of every description reigned supreme—that in those days an infant had hardly made its entrance into the world before it was brought into contact with the typhoid germ, and, if susceptible, contracted the disease, thereby obtaining immunity in after-life. We know how difficult it is to diagnose enteric fever in infancy—without a thermometer almost impossible. The prehistoric mother would notice her infant ailing, hot, probably with tympanitic abdomen, and diarrhœa. The prehistoric practitioner would say teething or a gastric attack, and who at the present day would blame him? Post-mortem examinations on infants in those days were even rarer than at present. The prehistoric practitioner never had a chance of seeing an adult suffering from enteric fever, and thus we hold him excused. Since the historic period (the days of sanitation) this filth disease, which undoubtedly depends on want of sanitation, has first made its appearance—surely a paradox, unless the above explanation is accepted. The sanitary development made it possible for children to escape, provided they were bred in a sanitary area; as they became older, on removal to a place of less perfect sanitation, they for the first time came into contact with the contagium and contracted the disease. This view is borne out by the following facts, extracted from a communication by the special correspondent of THE LANCET.[1] "The average death-rate of Toulon from typhoid fever is equal to 1·85 per 1000 per annum, and in this respect Toulon ranks next to Havre as the worst town in France. Yet it is well known that no permanent resident of Toulon dies from typhoid fever. This curious and significant fact I described when writing about Toulon some eight years ago. Dr. Galliot of the French Navy brought this forward in an essay for which the Government awarded him a gold medal. On calling the other day on him he again confirmed the fact. The natives of Toulon seem to be proof against typhoid fever. The children between the ages of three and six years, with but few exceptions, suffer from what is called in France *fièvre muqueuse*—an ill-defined fever which, though rarely fatal, confers immunity from typhoid fever. Dr. Galliot has demonstrated that since 1854 no native of Toulon has died from typhoid fever unless he had lost his immunity by living for several years in a thoroughly healthy town and then returned to the impurities of his native town. The victims of typhoid fever at Toulon are the strangers who come to live there; of these, of course, the greater number are soldiers."

Further strengthening evidence is shown in the following, extracted from the *British Medical Journal*.[2] Dr. Low, writing on the use of the water of the River Trent, states: "Persons freshly coming into the valley seem to be more commonly attacked than those whose lives have been spent in the district and who have been drinking for years of the river, the explanation being that, in all probability, many native Trentsiders have had enteric fever in early life, and that perhaps the constant use of Trent water by those who have not had the fever enables them in some way to resist more or less the disease." Similarly, in India and Egypt, both insanitary countries (in this respect resembling England

[1] THE LANCET, July 8th, 1893.
[2] Brit. Med. Jour., March 10th, 1894.

Digitized by Google

in the beginning of the present century) in which enteric fever prevails much among Europeans, especially the English, while it is unknown, or almost unknown, among the natives, the contention being that the latter have passed through the disease in infancy. The enormous infant mortality in these countries is to some extent corroborative evidence. These views are further borne out by what one sees in the army. It has been a standing conundrum why this disease appears to increase year by year among the troops abroad, while a few decades ago it was unknown. The cause has generally been attributed to the youth of the soldier of the present day. But formerly there were always at least some young soldiers present with the colours, yet these did not contract the fever, while many cases of enteric fever in men of mature age—from thirty-five to forty-five years of age—have of recent years come under my observation. The deduction is that the recruit of former times had passed through the ordeal in infancy, while he of the present day, being a more carefully nurtured article, escapes the disease in his own country only to be stricken by it directly he arrives in the insanitary areas which are the normal condition of the ordinary tropical or subtropical station.

A well-known South African expression, used for cattle, exactly meets the case: the recruit of former days was "salted," he of the present day is not. To exemplify further. Suppose a recruit born and bred in the slums of an insanitary English town, where typhoid fever is endemic. He will in all probability have passed through an attack of enteric fever, if susceptible to it, before he enlists. He may then go abroad with impunity, so far as enteric fever is concerned. This was the class of recruit of old days, when insanitation was universal. But, on the other hand, suppose a recruit, born and bred in a highly sanitary area—and such areas are becoming more common every day,—he will probably never have come in contact with the contagium before he enlists, and, having no protection, contracts the disease on arrival in an insanitary area. The conclusion from the above would be that the more protection afforded by sanitation to individuals in their native area, the more liability for them to contract the disease on removal to less favoured places, and that in the army an increasing amount of enteric fever must be anticipated until the foreign stations are brought into a sanitary condition as perfect as those at home.

Citadel Hospital, Cairo.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

RETROVERSION OF THE GRAVID UTERUS; SPONTANEOUS REPOSITION AT THE END OF THE FOURTH MONTH.

BY RICHARD H. READ, L.R.C.P. LOND., M.R.C.S.

A MARRIED woman consulted me on Aug. 7th, 1894. She was thirty years of age and had had eight children in the past nine years. She said she was between the third and fourth months of her ninth pregnancy. She complained of pains in the bowels and her urine was scanty. She was, however, able to do her ordinary housework, although the pains were severe at times. According to her statement, she had no difficulty with micturition or defecation. A few days later I saw her again, when she complained of diarrhœa. Her symptoms subsided under medicinal treatment, but as she still complained of abdominal pain and backache I examined her at her own house on Aug. 14th. The abdomen was distended, but was not markedly tender on palpation. There was a hard tumour extending from the pubes upwards to the umbilicus. At first it felt much like a gravid uterus, but on closer examination fluctuation was detected. The patient said this swelling had increased rapidly during the past fortnight. Per vaginam a smooth, rounded, elastic swelling was found pressing forward the posterior vaginal wall. Pressure upon this caused severe pain. The cervix uteri could not be felt, although a careful attempt was made to reach it. I had no catheter with me on this occasion. Next day, on making inquiry, the patient adhered to her statement that her micturition was performed naturally. On making pressure on the vaginal swelling a small quantity of urine flowed, and on passing a fine elastic male catheter a quantity of urine sufficient to fill an ordinary utensil once and a half was drawn off. The cervix still could not be felt, and the pelvic tumour seemed as fixed and tender as ever. I prescribed an opiate and ordered poultices to be applied to the lower half of the abdomen. The further progress of the case is interesting, inasmuch as though complete retention of urine followed the first use of the catheter and the patient was for some time in a critical condition with the pelvic tumour apparently as fixed within the pelvis as ever, the induction of abortion otherwise than by puncture (aspiration) through the uterine wall was rendered practically impossible by the position of the os uteri. All reasonable attempts at placing the pelvic tumour in a normal position with the patient in the ordinary and genu-pectoral postures failed. She was now (Aug. 22nd) at the end of the fourth month of pregnancy, and I decided to patiently wait another week before attempting further treatment, since her general health was improving somewhat and there were no signs of mischief around the uterus. After keeping the bladder and rectum empty for five days I was rewarded on the sixth morning, when I found the pregnant uterus in its normal position and the patient able to pass urine in the natural way. On Jan. 22nd, 1895, I delivered her of a male child at term. As the pains ceased soon after the os had been dilated the application of the forceps was necessary.

Hanley, Staffs.

TREPHINING AND DRAINAGE FOR BASAL CEREBRAL HÆMORRHAGE; DEATH.

BY FITZWILLIAM R. A. EVANS, L.R.C.P., L.R.C.S. IREL.

IN November, 1894, I was asked to see a girl aged five years who was said to have been suffering from whooping-cough for about a month previously. On examination I found her to be healthy, well developed, but troubled by occasional paroxysms of cough. She had a very good family history and had until then escaped all the ordinary infantile diseases. On the fourth morning I was sent for as the child had been found "stupid." On my arrival she was lying on her back in bed, motionless, quiet, with slow respiration and pulse, and the temperature normal. She did not notice or respond to questions. Her eyes were open; the pupils were dilated but equal, and reacted slowly to strong light, otherwise accommodation seemed to be constantly and completely relaxed. The membranes of both ears were normal. She moved her limbs lethargically when their cutaneous sensibility was tested, but without utterance or change of facial expression. All other signs were negative, poison excluded. No positive diagnosis was made then or treatment prescribed. Next day, on visiting the patient, the mother told me that the child had not passed urine or swallowed even liquids since I last saw her. The eyes were now fixed, there being no strabismus, but slight right ptosis. The right pupil was widely dilated and would not react; the left was much smaller, with some reaction. With the ophthalmoscope I saw that the right retinal veins were very turgid, the left being much less so. The knee-jerks were greatly exaggerated, particularly on the left side. While there appeared to be a general sensory and motor paresis, there was decided left hemiplegia. To avoid undue prolixity I may say that I diagnosed rupture of a basal cerebral vessel on or in the vicinity of the right side of the pons, with local and general compression, caused most likely by a paroxysm of coughing. I had the patient carried to my surgery and placed on the operating table, my friend, Mr. Graves, giving a little chloroform at first, which, however, we soon dispensed with. I applied a three-quarter inch trephine over the right parietal bone. When the disc was removed the dura mater bulged tensely into the aperture. After the membrane was incised the brain protruded. I then passed a No. 6 gum-elastic catheter downwards between the dura mater and the brain to the tentorium, along which the catheter seemed to slip to the neighbourhood of the pons. Uniformly blood-stained cerebro-spinal fluid to the amount of about three ounces escaped in the hour during which the catheter was allowed to remain *in situ*. The tension decreased, the pupils, especially the right, contracted and reacted, and the patient moaned. However, she never regained more than partial consciousness and died ten hours afterwards.

Remarks.—I selected the catheter in preference to a trocar, ı its flexibility it could follow the course of the ten- without wounding the sinuses or bloodvessels. Un- tely, I could not obtain a necropsy, but I think that :ory, signs, suddenness, and the result excluded every- :xcept hæmorrhage. In the ordinary cases of com- n, where the clot can be trephined over, the procedure y enough, and the results are often satisfactory. of the readers of THE LANCET—especially general ioners, like myself—have performed this operation :fully I should like to ascertain their *modus operandi*. ngham.

ERUPTION WITH RISE OF TEMPERATURE SIMULATING MEASLES.

By JAMES ROBERTSON, M.B., C.M. GLASG.

following case having occurred on board a Trans- : steamer may perhaps be of interest to medical of such vessels. The patient was a boy aged seven- onths, the child of Polish Jews on their way to the States of America. Two days before embarking he und to have on the centre of his left thigh a deep r sloughing ulcer an inch in diameter and with in- edges. The child was otherwise normal; there was hilitic history or sinus leading to bone. The ulcer ly resulted from an abscess; it was washed and l. Next day the child's pulse and respiration were his temperature was 101°F., and on his legs and arms vas a well-defined measly rash elevated and arranged les; a similar rash, though in a slight degree, was also nt on the body. On the following day the child's con- was unchanged and he was taken on board the ship.)ther and five other children ranging from three years lve, along with the patient, were all kept in hospital the voyage. On the second day at sea the rash dis- ed, having continued four days in all, the ulcer :d a healthy healing character, and the child became ise normal. He had no coryza or cough and throughout is food well. Was this a mild case of measles or was h simulating measles, but really due to absorption of oison from the ulcer? None of the six children ever asles; this child was the only one affected. There case of measles in the district where the family lived o embarkation, and no case occurred during the

sford-place, Glasgow.

TRIGEMINAL NEURALGIA AND NASAL DISEASE.

By MAYO COLLIER, F.R.C.S.

HIN the last twelve months two cases of severe and ent facial neuralgia that up to then had defied all treat- have come under my care; they were referred to me by my colleagues, Dr. Guthrie and Dr. Cagney of the North-West London Hospital. I have postponed till now publishing an abstract of these cases in order to try the validity of the cures by the test of time.

The first case was that of a man aged fifty who was for some time under the care of Dr. Turner, of the Hospital for Epilepsy and Paralysis, Regent's-park, and I am indebted to him for the early notes of this case. In short, this man had suffered severely for the last four years, and latterly the frequency, duration, and intensity of the attacks had made life almost unsupportable. An examination of the nasal cavities revealed extensive disease of the middle turbinated bone on the right side. The removal of this resulted in almost immediate as well as permanent and complete cure. The second case, that of a female aged thirty-eight kindly sent me by Dr. Cagney, was on all fours with the man's case, only of longer duration (twelve years) and at times greater intensity. An examination here revealed disease in the same situation, and the same fortunate result followed its removal. Of the many recorded cases of trigeminal neuralgia I find few attributed to nasal disease, but taking into consideration the wide distribution in the nasal cavities of the many branches of the nasal ganglion on the second division of the fifth nerve, it is not surprising that a considerable number of these cases are, in fact, due to irritation in one form or another of the branches of this nerve in the nose.

ST. MARYLEBONE INFIRMARY.

A CASE OF GRAVES' DISEASE ASSOCIATED WITH IDIOPATHIC MUSCULAR ATROPHY; REMARKS.

(Under the care of Dr. LULLUM WOOD BATHURST, late Second Assistant Medical Officer.)

A YOUTH aged twenty years was admitted into the St. Marylebone Infirmary complaining of difficulty in walking and weakness of his muscles. About fourteen months previously to his admission he found that in walking he bent over very much to the left side, and this caused his left ankle to ache; he then noticed that the toes of the left foot began to drop and the heel was drawn up so that he could not put it to the ground, and this has grown progressively worse up to the present time; for about two months previously to admission the right heel was being drawn up in the same way. He has had no actual pain in the limb, and only after walking for some time has he an aching sensation in the limbs, chiefly in the left ankle and thigh. For the last four months prior to admission he was unable to follow his employment, which entailed a good deal of walking. He has always enjoyed good health, never suffered from rheumatism or syphilis, and never drank to excess. His father died from phthisis. There is no history of any nervous complaints in the family. The patient is a tall young man with deeply pigmented skin and prominent eyes. His intellect is good. Though the exophthalmos is well marked von Graefe's sign cannot be obtained; the palate is highly arched; there is a prominence in the front of the neck corresponding to the position of the thyroid gland, and the swelling rises with deglutition; there is distinct pulsation over the tumour, but no dilated veins are visible. Slight tremors of the fingers are noticeable on the hands being held out in front of him. The skin of the body is very dark and of pigmented appearance, especially so on the face and abdomen. He complains of palpitation at times, though it does not worry him much. The apex beat is in the fourth space one inch outside the nipple line. The impulse is diffuse, forcible, and heaving. A thrill is felt over the cardiac area; cardiac dulness is increased slightly in an outward and downward direction. The first sound is loud and at times is accompanied by a short but distinct systolic murmur; this is not always audible. The heart's action is irregular and quick. As for the arms, the deltoids are somewhat wasted but can be put into action. The biceps muscle in each arm is almost completely wasted, and they appear to be simply fibrous cords, much contracted, so that the forearms cannot be completely extended. He cannot flex the elbows at all except by the weight of the forearms, for the biceps, brachialis anticus, and coraco-brachialis are atrophied. The power of extension of the elbow-joints is good, the triceps on each side acting well. He cannot pronate or supinate the forearms by muscular action, but there is slight power in the supinator longus. The upper arms are much wasted, but the forearms do not appear to be so. There is very slight power of extension of the wrists; power of flexion is fairly good. The tendon of the flexor carpi radialis is very prominent at the wrist, and on his flexing his hand a distinct clonus is felt in it. Coming to the thumbs, flexion and extension of the phalangeal joints are quite normal, but there is practically no power of flexion, extension, adduction, or abduction of the metacarpo-phalangeal joints. There is great wasting of the thenar eminences. In the face no paralysis, weakness, or wasting can be detected. On examining the neck, the sterno-mastoids and the anterior muscles of the neck seemed to be normal in size and contractile power, but the muscles of the back of the neck were rigid and contracted. He can hyper-extend the head—i.e., flex it on the back—easily, but cannot flex the

Digitized by Google

head on the sternum; this seems to be due to contraction of the posterior cervical muscles, for the anterior muscles are felt to be put into powerful action on his attempting to perform the act. As for the back, there is a lateral curvature in the dorsal region, with the concavity to the left, and a compensatory curve in the opposite direction in the lumbar region. The spinal muscles on the right side in the lumbar region are greatly thickened and feel like contracted tendons. The spine is kept absolutely rigid and cannot be flexed; this, as in the case of the neck, is due to the contracted condition of the erector spinæ. There is considerable lordosis of the lumbar spine. The trapezii on both sides act well and powerfully; the shoulders can be shrugged and thrown back. The serrati magni appear to be weak, and lunging can be only imperfectly performed; the vertical edges of the scapulæ stand out prominently. The angles of the ribs are more prominent on the right side, with corresponding prominence of the left side of the chest in front. The respiration is partly thoracic and partly abdominal; the recti and other abdominal muscles contract well. There is some wasting of the muscles of the thigh and calf in either leg, but the muscles contract well, with the exception of the gluteal muscles, which are soft and flabby, and have scarcely any power of contraction. The feet are in a position of talipes equino-varus, especially the left, the head of the astragalus on that side being very prominent. The toes of the left foot are dorsiflexed at the metatarso-phalangeal joints, and the heel is drawn up; the same condition exists in the right foot, but to a much less extent. Neither foot can be everted, nor can the feet be dorsiflexed at the ankle-joints. On attempting to do so the deformity is increased. Coming to the nervous system, sensation both to touch and to heat and cold is good. The pupils react to light and accommodation, and there is no abnormality in the retinæ. The patellar reflexes are absent; the plantar reflexes are normal or rather exaggerated; while the cremasteric and abdominal reflexes are very active. The reaction of the muscles to faradaism is rather increased, otherwise electric excitability is normal. In walking neither heel can be made to touch the ground, the patient treading only on the balls of his toes with the heels about three inches from the floor. He is very unsteady, the knees knocking together and the feet tending to cross. The body rolls from side to side. There is extreme lordosis of the lumbar spine, and the gluteal muscles are quite relaxed. When lying flat on his back he cannot raise himself into a sitting posture without the help of his arms; on attempting to do so he raises himself a little by the aid of his abdominal wall muscles. The inability must be due either to weakness of the anterior spinal muscles (psoas and quadrati lumborum), together with the abdominal wall muscles, or to the intense rigidity and contraction of the components of the erector spinæ; probably the latter would be quite sufficient to account for it. Having been helped into the kneeling posture he is quite unable to rise without aiding himself with his arms. This, again, shows the inaction of the glutei muscles, which are quite flaccid during the attempt. On raising him on to his legs he is able easily to straighten the back up into the erect position without pushing off his thighs. He is quite unable to rise from a chair unaided by his arms. There is no incontinence or retention of urine, and he has good control over the sphincters.

Remarks by Dr. BATHURST. — Dr. BEEVOR, who saw the case several times and took great interest in it, was of the opinion that it was one of exophthalmic goitre associated with idiopathic muscular atrophy, but it was possible that it might be an unusual form of pseudo-hypertrophic paralysis. He regarded the contracted condition of the erector spinæ as most unusual. For permission to publish this case I am indebted to Mr. J. R. Lunn, medical superintendent of the infirmary.

SALVATION ARMY SHELTERS AND SMALL-POX.—On Aug. 27th at Clerkenwell the police reported that a cab-driver, who was remanded last week on a charge of stealing from Upper-street, Islington, a horse and hansom cab, value £76, the property of Arthur Thomas Young, was unable to attend the court. Since he had been on remand he had developed small-pox, and had been removed to the hospital When charged he gave his address at the Salvation Army Shelter, Charles-street, Hatton-garden.

Reviews and Notices of Books.

A Text-book of Physiology. By M. FOSTER, M.D., Professor of Physiology in the University of Cambridge. With Illustrations. Sixth edition. Part II. London: Macmillan and Co. 1895.

THIS part embraces the tissues of chemical action with their respective mechanisms and nutrition. It, therefore, includes salivary, gastric, and intestinal digestion, respiration, and the lacteal, the urinary, and cutaneous secretions. We suppose that the last chapters had gone to press before the author had the opportunity of hearing of the remarkable experiments of Professor Schäfer on the action of the extract of the medullary portion of the adrenals on the blood pressure. So short a period has elapsed since the appearance of the last edition of this part of Professor Foster's work that little is required to bring it up to date. The present part has, however, been increased by about forty pages, and it possesses a separate index, which was much required in the editions of 1891 and 1889.

The additions to and corrections of the text that have been made are in the earlier sections very slight. Thus, for example, whilst in the previous edition it was stated that the branches of Auerbach's and Meissner's plexuses were distributed to the muscular coats of the stomach, in this edition it is added that, whilst many of the fibres are thus distributed, others go to the muscular fibres of the blood-vessels, and some, there is reason to think, "are destined for the glands and end in delicate arborescent terminations in contact with the substance of the cells." It is of such intercalations that the increase in bulk is made up, and the work is maintained as a whole at the high level it has reached.

Medical Handbook of Life Assurance for the use of Medical and other Officers of Companies. By JAMES EDWARD POLLOCK, M.D., F.R.C.P., Consulting Physician to the Hospital for Consumption and Diseases of the Chest, Physician to the Imperial Life Office &c., President of the Life Assurance Medical Officers' Association; and JAMES CHISHOLM, General Manager and Actuary of the Imperial Life Insurance Company. Fourth edition. London, Paris, and Melbourne: Cassell and Co. 1895.

ALTHOUGH the study of the medical questions involved in life assurance tends to become a special department of practice, the subject is one with the general details of which all medical men ought to gain some acquaintance. Proposers often consult their ordinary medical adviser before opening negotiations with an office, and in the numerous cases where the life is neither young nor first class, regarded from an assurance point of view, the family practitioner is not unlikely to be referred to by one side or the other in the course of the business. Dr. Pollock is to be congratulated on his success in providing for his professional brethren a handy and reliable guide to this complicated subject, in which mere precision of physical examination has to be so largely supplemented by the practical teachings of mature experience, by inferences from family histories, and by intuitive generalisations which not everyone can accomplish profitably. His directions for the investigation of cases aim at the eliciting of all the facts. The proposer's interviews with the medical man acting for the company should invariably be private, the interrogatories should be suave and tactful, the physical examination of the chest and abdomen should in all cases be made next the skin, and chemical examination of the urine in every instance is recommended. Albuminuria formerly existing, but followed by a period of perfect health continuing for years, need not disqualify. Albuminuria presently existing and known to have existed for years in persons of otherwise perfect health may justify assurance for a

Digitized by Google

short period with an addition to the premium. Cases of albuminuria associated with symptoms of Bright's disease, cardiac disease, gout or rheumatism should be declined. Glycosuria should forbid acceptance of the life, but if it has entirely disappeared for some years the life might be insured with some addition to the premium. Gout and intemperance are prominent among the conditions which result in loss to the insurance company. Dr. Pollock accordingly devotes much attention to them, and explains how these extra risks have to be met either by additions to the age or additions to the premium. The inferences to be drawn from the results of physical examination are explained in much detail, and readers will be greatly assisted in their comprehension of the subject by a series of one hundred typical cases selected from the records of various offices. In these the leading clinical symptoms are summarised in a line or two, and such extra rating as may be based thereon is also shown.

Chemistry of Urine. A Practical Guide to the Analytical Examination of Diabetic, Albuminous, and Gouty Urine. By ALFRED H. ALLEN, F.I.C., F.C.S. London: J. & A. Churchill. 1895.

MR. ALLEN'S contributions to the literature of analytical chemistry are well known and highly valued, because a critical and practical examination of the processes which he describes brings home the assurance that the author speaks not only of that he knows about, but of that he has tried. Analytical chemists have long recognised his work on "Commercial Organic Analysis," which we have reviewed in these columns,[1] as a distinctly reliable book of reference on all matters pertaining to the analysis of various organic stuffs. It contains just those precautionary injunctions and recommendations as to the best and most satisfactory methods of analysis which only practical acquaintance can enable an author to write about with any real or useful purpose. We welcome, therefore, the issue by the same author of a work on urinary analysis, since it is reasonable to suppose that the same confidence may be placed in the observations which he is led to make as to the merits and demerits of the various analytical methods that have been suggested and employed in the important task of differentiating between a healthy and a morbid urine. It is remarked in the preface that a considerable portion of the contents of the book was designed to form part of the concluding volume of the work we have already alluded to—"Commercial Organic Analysis"—Part 3 of Vol. III. of which deals mainly with substances of animal origin, and which he announces will complete the chief literary work of his life. "Of late, however," he goes on to say, "circumstances have led me to devote much attention to the chemical examination of urine, especially in relation to certain pathological conditions of great importance in Life Assurance reports [why life and assurance in capitals, by the way?] as well as in clinical diagnosis and prognosis. These examinations have caused me to investigate critically a large number of the analytical methods which are in vogue for the examination of urine, especially for sugar and albumin, and to confirm or disprove certain statements generally accepted as facts." The publication of the work is sufficiently "up to date" as to have admitted of a digest of the opinions expressed, amongst others, by Dr. Pavy, Sir George Johnson, Dr. Halliburton, and Mr. Allen himself on the somewhat vexed question of the presence of a small quantity of sugar in normal urine, which formed the subject of considerable and lengthy correspondence in our columns early in the present year.[2] The last word, as the author admits, is doubtless yet to be said. And there still probably remain some important points to be cleared up in regard to the possibly disturbing effects of the reagents used in the processes employed for the separation of the sugar, and the question of their action upon bodies not sugar. The book is not burdened with details of processes out of use or of those methods merely now of interest in connexion with the history of the subject; but it is a clear and practical guide to the analytical examination of urine, giving concise and readily comprehensible directions of only those processes which are worthy of recommendation or which, in other words, involve a minimum of trouble, occupy a reasonably short time, and yet afford accurate results—points which are of primary importance to the busy practitioner. One omission has come under our notice—there is no mention of Pettenkofer's well-known and useful test for biliary pigments. We may add that we have found this test more satisfactory by substituting a solution of glucose in strong sulphuric acid for ordinary cane sugar, which is apt to char and therefore to mask any colour that may be produced. Glucose may be dissolved, with little change of colour, in strong sulphuric acid, and when a few drops of this solution are allowed to fall into the centre of a small pool of urine upon a white plate the play of colours due to biliary pigments may be seen under very advantageous conditions.

Conventional Lies of our Civilisation. By MAX NORDAU London: William Heinemann. 17*s*.

"WHAT is truth?" was a question asked upon an occasion which, *pace* Max Nordau, had a great influence upon the future course of the world, and in this book—an earlier work than "Degeneration"—Max Nordau has set himself to answer the question more or less.

The whole civilised world, according to him, is hollow and rotten; we are all miserable and striving to get away from our age and its disappointments, and the reason of this pessimism is that all our institutions, all the existing conditions of the world, are at war with our recent convictions. Religion, kings, aristocracy, marriage, and everything else are all lies, and according to Max Nordau everyone knows them for such. We leave it for skilled casuists to decide whether a lie which everyone knows to be a lie is really so, and we doubt whether if we all lived in the Palace of Truth we should be much happier. To "let innumerable cats out of unnumbered bags" would not in the least degree lessen social inequalities or reduce the number of illness, but despite Max Nordau's gloomy views the world is a better place than it was and men are grown kindlier one towards another.

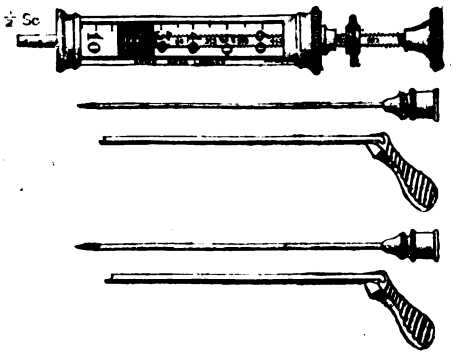
The book is well worth reading, for if anyone is inclined to quarrel with this age he will be more satisfied with it when he has read this indictment of modern life.

OUR LIBRARY TABLE.

Bulletin de la Société de Pathologie et d'Hygiène Coloniale. Paris: Paul Lemaire. 1895.—This is a monthly publication, which began with this year and consists of thirty-two pages. As is only natural, our neighbours are chiefly interested in the tropical diseases which affect their colonies, and most of the contributions have, so far, had reference to Madagascar, Haïti, the Lower Senegal, Tonquin, the Niger, Tunis, and the French Soudan; but we see in the June and July numbers that a translation is published of Dr. Sandwith's paper on Anchylostomiasis, which first appeared in our columns.[1] Some very useful advice has been given to intending colonists who desire to preserve their health, and in the

[1] THE LANCET, June 2nd, 1894.

Digitized by Google



interests of tropical medicine we gladly welcome this new arrival.

Diabetes and its Treatment. By A. VINTRAS, M.D. London: Baillière, Tindall, and Cox. 1895.—This little book of twenty-four pages does not pretend to discuss the difficult question of the pathology of diabetes, and the treatment recommended is the lithia and arsenic method recommended by Dr Martineau, which Dr. Vintras has adopted on the principle of having seen very good results accruing from it. The diet, rules, and hints at the end of the book will be much appreciated by the diabetic as helping to vary the monotony of his food.

New Inventions.

A MODIFICATION OF THE EXPLORING TROCAR.

I BEG to introduce to the profession a modification of the exploring trocar which I think will be found to be useful in the treatment of such collections of fluid as localised empyemata, abscess of the lung, and deep abscesses of the neck and pelvis. I have experienced in my own operations and witnessed in those of others sometimes a difficulty in cutting into an abscess which has been proved to exist by the ordinary exploring needle, and it struck me that if we had a guide on the needle that could be left *in situ* after the needle was withdrawn some operations would be greatly facilitated. I have therefore had made a fine director, to which a suitable handle is attached, fitted on to an exploring

needle. The director very slightly increases the thickness of the needle. The instrument is used with the director encasing the needle; pus having been found, the syringe and needle are withdrawn together, and the director, which can be held steady by the firm handle, serves as a guide for a knife, or in dangerous regions for a sinus forceps to be run down the groove. The instrument has been excellently made for me by Messrs. Down Brothers, 5 and 7, St. Thomas's-street. London, S.E.

ARTHUR W. PRICHARD,
Surgeon, Bristol Royal Infirmary.

COINCIDENCES IN PRACTICE.

BY WILLIAM O'NEILL, M.D., M.R.C.P. LOND., &C.,
LATE PHYSICIAN TO THE LINCOLN LUNATIC HOSPITAL AND PHYSICIAN TO THE LINCOLN GENERAL DISPENSARY, &C.

So many coincidences are met with in the course of medical practice that it would almost seem that diseases and accidents, like sorrows, never come singly. The only cases of glanders in man that I have seen were two in number, and they occurred within a week without having any connexion with one another. A surgical friend recently mentioned the fact that on the preceding evening he had treated two cases of fractured arms in children, although for a long time previously he had not had a similar case. I heard a country practitioner say that he had at the time of speaking three cases of fractured legs under his care, a thing to him unprecedented. It would be easy to multiply examples bearing on the same subject, if it were necessary, to mention occurrences which must be in the experience of every medical man. In the autumn of 1894 and in the early part of the late winter I treated only a few cases of hæmorrhage, chiefly hemoptysis in phthisical patients; but in the month of March quite suddenly a considerable number of cases of bleeding of various kinds came under my observation. These might be explained, perhaps, by atmospheric influences and were not strictly coincidences like the preceding examples, but still they were non-contagious diseases that did not come singly.

Among the cases of hæmorrhage were two or three of interest. One of them was a case of epileptiform convulsions from loss of blood. The subject of the attack was a man about forty-nine years of age who, after getting out of bed in the night to micturate, suddenly fell on the floor insensible and became immediately convulsed, especially on the left side. He gradually regained consciousness, but in less than an hour he was convulsed again. The second attack subsided in the course of a few minutes. The patient then appeared ghastly white and complained of headache, muscular twitchings of the left side of the head, and great prostration of strength. In the course of the day he was profusely purged, the stools being melænic, and this character of the evacuations continued for three or four days. The patient had suffered from painful digestion for several years, but on no previous occasion had he lost blood or been convulsed.

Another case was that of a woman fifty years of age, who consulted me on account of disagreeable sensations in the region of the bladder and scanty flow of urine. On the third day after my seeing her she commenced to void blood with her urine. This was followed by a flow of blood from the nostrils and mouth, and her loose motions also gave evidence that blood was escaping from the intestinal tract. In addition the skin presented patches of ecchymosis, especially wherever the slightest pressure had been made. For two or three days the patient's temperature was increased and her face flushed, but with these exceptions there were no indications of fever, and the only complaint she made was of headache and debility. When this patient was eighteen years of age she had a similar attack, but much milder in character, and a few years ago she had a tooth extracted which caused bleeding so profuse and so prolonged that the dentist declared he would never touch one of her teeth again.

Among the cases of hæmoptysis was an old patient who had suffered from phthisis for upwards of twenty years. One Sunday in the month of June, 1875, he was carried out of a chapel coughing up blood. The day was hot, the congregation large, and he felt oppressed; but before he could get into the fresh air the bleeding came on. He quickly recovered from this attack, but, strange to say, on the corresponding Sunday of the following year a similar occurrence took place. Since then scarcely two years pass without the patient having an attack of bleeding more or less profuse which brings him to death's door. Then when things seem to be at the worst he begins to improve, and this is his condition at the present time.

All the patients afflicted with hæmorrhage suffered from little or no pain with the exception of one or two. In a case of renal hæmorrhage the result of a calculus, the pain which a patient endured for a day or two was very great. From the effects of the hæmorrhage, however, all the patients recovered, and this was a happy consummation for patients and physician. In the case of hæmophilia ergot was of the greatest service, although the drug is not recommended in such cases by some writers.

Lincoln.

THE PORTSMOUTH INFECTIOUS HOSPITAL.—The borough auditors of Portsmouth (Mr. H. B. Morris and Mr. E. E. Hanham) issued their report on Friday, the 23rd inst., on the general municipal and urban sanitary authority's accounts and books for the past year. Every department is dealt with at length, and regarding the health department they say: "We are glad to note that our suggestions, as to the day-book being a complete register of all the patients admitted to the infectious diseases hospital and the charge made being inserted against each name, have been adopted. We note a considerable increase in the amount recovered from patients in the hospital."

Digitized by Google

THE LANCET.

LONDON: SATURDAY, AUGUST 31, 1895.

THE question of the remuneration of medical witnesses for attending and giving evidence in courts of law has always been a contentious one, and we fear there is little likelihood of establishing a scale of fees that would be acceptable to members of the profession and intending litigants. Much, however, might be done in the matter of fixing an equitable payment of fees where the courts have the authority of ordering such payment. A medical man is not bound to give evidence on matters of opinion, but he must answer his subpœna on questions of fact like any other witness. It is difficult, however, to dissociate the two cases, for it rarely happens that professional testimony is required except where inferences constitute its essential value. As regards civil actions it has been submitted—(1) that a medical witness should have an entirely free hand in coming to terms with his intended clients—that he should be unfettered by rules of practice or rules of court; (2) that he ought to be satisfied with the regulation conduct fee claimable on receiving his subpœna; and (3) that in certain cases he ought to give evidence and furnish reports *gratuitously*. The first suggestion is, in our opinion, the only tenable one; for otherwise, whilst protection and relief might be given to impecunious yet deserving persons, the door would be opened to others in a position of competence, or even affluence, who would not scruple to take advantage of regulations never intended for their benefit. In the case, say, of a poor man who had been injured, possibly through no fault of his own, it is certainly hard, when he makes a claim for compensation, that he should be unable to support such claim by medical evidence simply because he cannot afford that which some have termed a luxury, but which in reality is necessary to establish his plea. At the same time, it is idle to contend that the medical man who has treated him should be compelled to attend the court and give evidence without a guarantee of remuneration. The plaintiff, let us suppose, is wholly incapable of making good a promise of payment unless he succeeds in his action. It is clear the defendant will not be moved by a spirit of friendly feeling towards the medical attendant of his opponent, and would only pay on judgment against him. The members of our profession have equally "a tear for pity and a hand open as day for melting charity" with other sections of the community but were they on all occasions compelled to be the bright examples, we fear that at no distant date they would be the victims of misplaced confidence and over-exacting claims, for

> "Goodness growing to a plurisy
> Dies of its own too much."

At a recent trial the Common Serjeant made some strong remarks on the duties of hospital surgeons as witnesses "being of opinion that a plaintiff ought to receive a report without any fee; and for a hospital surgeon to demand one and to refuse to give evidence unless he received another fee he thought an improper proceeding." With all submission we directly challenge the contention of the learned judge. We are obviously not in a position to pose as authorities on purely legal matters, but we would suggest that "a report" for the purposes of litigation would be practically valueless. Would the Common Serjeant admit such as coming within the laws of evidence? We think not. For without supplementary personal testimony, where would be the justice to the defendant, who has the right of challenging and testing the value of such testimony by cross-examination? Moreover, on other grounds we demur to his opinion. A hospital surgeon, whether visiting or resident, in many cases serves without any remuneration whatever, and when paid receives in most instances a poor equivalent. We do not complain of this, but we certainly think that he should not be at the beck and call of every claimant patient, not only for his own sake, but even more for that of the many other sufferers under his charge, who, by his perhaps repeated and protracted absence, would not receive the attention they deserve and have a right to demand. No; if medical testimony must be forthcoming there should be some rule sanctioned by the Home Secretary or other official such as obtains in the police-courts, under which a medical man's attendance and evidence meet with some pecuniary recognition.

The existing scales of fees for travelling expenses and for the services of medical men as witnesses in the different courts require regulating with a view to fairness of payment and greater uniformity. Under existing conditions a practitioner if called to attend an Assize Court distant from home is not allowed anything for Sundays, even though it is impossible to leave the locality of the court. This is an injustice to which we have referred on many occasions. The law moves slowly in matters of reform, but we would again urge the right of our professional brethren to their undoubted dues.

IN a recent issue of the *Journal of Comparative Pathology and Therapeutics* there is an instructive paper by Professor HOBDAY, of the London Veterinary College, on the Therapeutic Uses and Toxicological Effects of Cocaine in the Horse, Dog, and Cat. He performed a considerable number of experiments on these animals with this drug, the result of which lend additional support to facts already acquired with regard to its usefulness as a local anæsthetic as well as to the danger that may attend its injudicious application. He was led to institute these experiments from an accident that happened to a dog about to be submitted to an operation, into which the student injected subcutaneously about twenty minims of cocaine in each of six or eight places, the animal—a mongrel spaniel—receiving altogether about sixteen grains of this drug. This produced frenzy, convulsions, and the other indications of cocaine poisoning, and death ensued within ten minutes.

Its therapeutic value as a local anæsthetic in superficial operations on the eyes of horses, dogs, and cats is shown by a number of cases in which foreign bodies, tumours, and the membrana nictitans were painlessly removed, as well as

Digitized by Google

eyelids sutured without any difficulty. Its anæsthetic action when applied locally to parts where the skin is tender, thin, or denuded of hair was demonstrated in various instances in which horses had the actual cautery applied for exostosis on the phalanges and other morbid conditions, as well as in division of sensory nerves of the limbs for navicular disease. In the latter cases the solution of cocaine was first injected subcutaneously, then the skin over the nerve was incised, and some of the solution (twenty minims) poured into the connective tissue directly on to the nerve itself; this when cut and a portion removed did not produce any evidence of pain. Mammary and other tumours were also removed from dogs and horses without occasioning any manifestation of uneasiness from the operation, though in some instances the constitutional effects of the drug were exhibited in a more or less marked manner. The toxic action of cocaine on horses, donkeys, dogs, and cats was distinctly shown in various operations, as well as in some experiments, death resulting in some instances after the exhibition of characteristic symptoms, which would undoubtedly interfere with the carrying out of delicate operations. Cases are detailed which would go to prove that cocaine is readily absorbed into the system from serous and mucous surfaces, and that it might be useful in allaying irritation of the stomach by its action on the nerve terminals in the lining membrane of that organ. The fact that cocaine, when brought into contact with a large nerve trunk, will cause anæsthesia of all parts supplied by that trunk below the seat of injection, can be utilised as a valuable aid to diagnosis in certain cases of obscure lameness in horses, was demonstrated in a number of cases recorded by Professor HOBDAY, in which foot lameness was proved to be present by its temporary disappearance after subcutaneous injection of the drug over the metacarpal nerves. The observation made in France that cocaine will diminish the lacteal secretion of animals when applied to the mammary glands was corroborated by the case of a bitch which, when in full milk, had the mamma painted four times daily with a solution composed of five grains of cocaine hydrochlor., one ounce of water, and half an ounce of glycerine. In three days the secretion was very perceptibly decreased, and it had almost ceased in five days.

Professor HOBDAY concludes that there is no absolutely certain antidote to cocaine, though he gives instances which show that opium and amyl nitrite have the power of antagonising the spasms, the latter drug doing this when inhaled or administered hypodermically. The drug was used in no fewer than ninty-nine cases, and the conclusions derived therefrom by Professor HOBDAY are to the following effect:—1. Its therapeutic value in certain cases is unquestionable, but its use in all animals is attended with danger unless proper care is taken to estimate the amount which can be employed with safety. 2. It can readily be absorbed from subcutaneous, serous, or mucous tissues, and is of value as a local anæsthetic in surgery and in certain affections of the stomach—though in surgery there is danger of interference with the operation if too large a dose, not necessarily toxic, be given because of the violent involuntary clonic spasms of the voluntary muscles. 3. The safe and effective subcutaneous dose for the horse is not more than ten or twelve grains, for the dog from two to four grains (by the mouth one to four grains), and for the cat and delicate breeds of dogs not more than one grain. 4. The first sign of danger is great uneasiness, followed by powerful involuntary clonic spasm of the voluntary muscles of the body, especially those of the jaws and limbs. 5. If a diseased condition of the heart or lungs, especially the latter, be suspected, great care must be observed and a minimum dose given. 6. The anæsthetic effect is only manifested locally and around the seat of inoculation from half an inch to an inch and a half, not extending to the deeper tissues, the anæsthesia occurring in from three to five minutes and continuing for about twenty to twenty-five minutes. 7. Toxic doses, subcutaneously, and allowing for idiosyncrasies, are for the dog from three to six grains, and for the cat from two to four grains. The symptoms due to a poisonous dose are enumerated and are as follows. In from two to four minutes after subcutaneous administration the animal becomes unusually quiet if undisturbed; there are constant licking of the lips, and often a smacking sound, increased flow of thin watery saliva, which collects at the back of the pharynx and dribbles from the lips, sometimes interfering with respiration and causing constant gulping and apparently a choking sensation. The animal is very sensitive to all sounds, and attentive when spoken to, and the ears are moved backwards and forwards. Uneasiness then ensues, followed in from two to twenty minutes by the violent clonic spasms already alluded to, which occur about every fifteen seconds and rapidly lead to exhaustion, as the animal appears to be quite unconscious. A curious effect of cocaine on the motor nerves was noted in dogs affected with chorea. Animals so affected, and which could not proceed five yards without staggering and falling, after receiving a dose could walk quite well and appeared bright and cheerful. This effect was very transient, however, and the after-effects were not favourable.

IN his recent Croonian Lectures Dr. MARCET touches on a subject which deserves more attention than is commonly accorded to it—viz., the training of the muscular acts involved in respiration, with the view of combating certain morbid conditions. The case to which Dr. MARCET more particularly refers is that of asthma, which he believes to be due in part at least to a deficient supply of oxygen to the respiratory centres. "Why," he asks, "should not asthma yield to the training of the respiration, carried out by practising the respiratory movements wanted to carry the tidal air through the lungs to oxidise the blood and emit the carbonic acid, while imparting to the circulation a better tendency to work in perfect harmony with the respiratory requirements?" The lecturer professes to have made practical trial of this idea in only one case, but with complete success, and the suggestion is worthy of attention. That asthma is attended by a deficiency of oxygen in the blood is probable, but it is open to question whether this is the cause or the consequence of the affection. The severity of the paroxysms and their remarked periodicity, together with the immunity of the patient in the intervals, suggest that some derangement of the nervous mechanism is at work, but it is quite conceivable that an accumulation of carbonic acid in the blood supplying the nerve centres may

Digitized by Google

play a real and large part in the determination of the symptoms of the disease. If this view be well founded, systematic physical exercise directed especially to the play of the respiratory function would offer hope of benefit in the treatment of asthmatics.

The question is, however, a much wider one. How much imperfect development and feeble vitality, how much indifferent health and minor derangement of function, how much phthisis and other pulmonary disease is due to this single cause—viz., the neglect of systematic training of the breathing—would be difficult of determination, but the amount of mischief attributable to this cause is undoubtedly large. In the education of the young this point was long wholly neglected, but, happily, a remedy was in many cases unconsciously applied. Most games practised at schools involve fairly thorough and satisfactory, though undesigned, respiratory gymnastics. Calisthenics, which now form part of the ordinary school régime, though primarily intended for the development of the muscular system generally, are also efficient for the development of respiratory power. In some schools the art of breathing is systematically taught. It is a comparatively simple matter to insist without fussiness or undue self-consciousness upon the great importance of cultivating the habit of taking regular and full respirations, more especially when in the open air, and exercising with a view to health. Such a habit has many indirect as well as direct advantages. Not only does it strengthen the respiratory mechanisms, but it helps to purify the blood, to heighten the general vitality, and to obviate the tendency to certain diseases. There can be little doubt that one of the most fruitful causes of phthisis is imperfect expansion of the lungs, leading to the accumulation of insufficiently oxygenated air, which affords a nidus favourable to the development of the bacillus of tubercle. The fact that tubercle shows such a decided preference for the apices—i.e., for the least expansile portion of the lungs—is a strong corroboration of this view. Hence, in early cases of phthisis, where there is little or no pyrexia or wasting, success in treatment often follows measures designed to promote pulmonary expansion. Regulated exercise, riding, cycling, cricket, golf, judicious mountaineering, are often of signal benefit in such cases, and it seems probable that they operate chiefly by promoting a more efficient performance of the respiratory function. No doubt we must choose our cases with caution, and the off-hand recommendation of exercise, fresh air, and change of climate to phthisical patients is most deplorable. In many cases rest and quiet are rather to be enjoined, but the distinction between the two classes of patient is not as a rule very difficult to draw. What we wish to emphasise is the view that where the absence of acute symptoms permits the treatment of phthisis by the more robust methods the importance of a systematic development of the respiratory function should never be lost sight of. In this connexion the practitioner will do well to bear in mind the value in certain cases of the cultivation of any gift for singing that the patient may happen to possess. That the cautious and judicious practice of these various forms of respiratory gymnastics tends to hæmorrhage is, we think, a mistake. No doubt, this point is worthy of the utmost care and attention, but we think experience shows that in a large proportion of cases pulmonary hæmorrhage does not follow upon exertion, and that it is comparatively somewhat frequent at night and in the early hours of the morning, when the patient has been for some time at rest. Of course, we do not for a moment question the necessity for rest when hæmorrhage either actually exists or has recently occurred.

There is another condition in which respiratory gymnastics are probably the most essential point in treatment—viz., stammering. No doubt there are various types and grades of this disagreeable infirmity, and more than one cause for it exists; but in a large proportion of cases the crucial point is the inability of the sufferer to control his respiratory function. In this case persistent and persevering training will often effect the happiest results. The patient must be taught how to breathe regularly and efficiently, and if this can be effected his defects of vocalisation and articulation will often be easily overcome. It is a great point gained when he comes to realise clearly that his malady is not a mysterious and hopeless affection, but, to a large extent at least, simply an inability to control the breathing. The neglect of the whole subject of systematised breathing is probably owing to the feeling that it is too obvious a matter to require any instruction. Many take it too much for granted that breathing is an instinctive act which requires no training for its efficient performance. We hope we have said enough to show that this view of the subject is a mistaken one.

Annotations.

"Ne quid nimis."

THE DANGER OF TINNED FOODS.

IT is admittedly difficult to reach the "masses," but we think it is the duty of every conceivable agency—the press, "those who know," and even the pulpit—to warn the people of the grave danger of eating tinned foods that have been exposed to the air some time after opening. We should have thought that the cases of wholesale poisoning that have been reported in the newspapers from time to time would have sufficiently placed the public on their guard in this matter; another case, however, comes from Wakefield, in Yorkshire. It appears that a Mrs. Firth bought a tin of salmon which she kept in the house for a few days and then opened. Now she might have kept it unopened for a few months or even much longer without any reason to suppose that it would have been unwholesome so long as the contents of the tin were sound and the ends concave, but the tinned fish was exposed to the air and warmth some time, with the result that when her husband ate a portion for tea he was seized not long afterwards with violent and well-nigh intolerable pains in the back, which culminated in "a night of great agony." A little girl who had partaken of the same tinned fish complained also of sickness, gastric pain, and diarrhœa. Happily there is hope of recovery for both, though, as in most cases of acute poisoning, the progress towards this end must be slow. While the exact manner in which poisonous substances—ptomaines—are produced so rapidly is not known with certitude, the fact that they are produced in sufficient quantity to cause very grave symptoms of poisoning has been brought out in a multitude of cases. It is of the utmost importance to observe, however, that in these instances where such things as meat, fish,

Digitized by Google

pâtés, &c. were consumed when fresh each and all proved perfectly wholesome; but the very same viands when eaten one day or a few days later occasioned the most severe sickness. In one well-known case in particular the first half of the contents of a tin of lobster was consumed with no ill effect, but the rest a few days afterwards proved extremely poisonous. We have not one word to say against the use of tinned provisions so long as they are turned out of the tin in good condition. There is, indeed, no ground for doubting their wholesomeness, and in many instances they supply a real need; but consumers of these preserved viands, who, we think, belong mostly to the poorer classes, must be warned of the very real danger which may result from eating them after a day or longer of exposure to the air. As a safeguard, and without injuring their interests, could not the manufacturers of these commodities be induced to label the tins to some such effect as follows?—"The contents of this tin are perfectly wholesome when eaten fresh from the tin and afford good food, but the public are advised not to expose the contents for any length of time to the injurious influences of the atmosphere." It is simply a question of degree. Fresh butcher's meat is wholesome food enough, but there is the same risk attached to eating it if it exhibits signs of putrescence as there is in the case of tinned foods. Either will "turn" after a few days' exposure to the air. We go further, and venture to suggest that some such warning placed upon the label might be insisted upon by the Legislature.

THE HEAT AND THE LATE MILITARY MARCH.

THE number of soldiers who fell out during the late march from Aldershot to the New Forest has been productive of a good deal of attention and comment. There is no doubt that a considerable amount of temporary inefficiency was caused by the heat and fatigue—especially among the young soldiers—on this as on some previous occasions. The heat, which occurred suddenly and lasted only for a short time, was by all accounts exceptionally great, and young soldiers of the British Army bear heat badly until they have undergone some training and become accustomed to it and to the carrying of their arms and equipment in the course of marching. Some of the most remarkable marches on record have been made, however, by the British Army, but the soldiers have been in excellent training at the time and usually mature and well developed. As far as we can learn, the military authorities exercised all practicable care and consideration. On occasions of this kind it is to be remembered that there is commonly some leave-taking and jollification beforehand, and the men do not always start on a march in the best condition possible. Temperance in all things, bathing and cleanliness, light porous clothing, and very open order in marching—the marches being undertaken early in the morning or in the evening when there is moonlight—with halts *en route*, are the best and most common-sense safeguards against the effects of heat. But young and immature soldiers—mere lads—always bear heat, fatigue, and weight-carrying badly, notwithstanding their remarkable recuperative powers.

THE EMOLUMENTS OF AN EXECUTIONER.

M. DEIBLER'S name having been a good deal before the Parisian public lately in connexion with a case which he lost in the law courts, advantage has been taken of the circumstance by the crotcheteers, who are ever ready to seize upon any excuse, however flimsy, in order to call attention to their pet conceits. The partisans of "economy at all costs," for instance, maintain that the gruesome official's emoluments are far too high, and demand a reduction of at least one-half; while the opponents of capital punishment would carry out a still more fundamental retrenchment by abolishing the post altogether. "Without seeking to advocate or contest the opinions of one side rather than the other," says *Le Progrès Médical*, to whom we are indebted for the above information, "it seems to us that the subjoined record extracted from the archives of old Paris possesses sufficient interest to warrant its publication. Our readers will see from it what a terrible thing the capital penalty was in former days and at the same time learn that the gentlemen who acted as executioners, with their assistants and torturers, did not labour for glory alone."

DEATH UNDER CHLOROFORM.

A CASE of more than usual interest is reported by the *Bombay Gazette*. A male native aged fifty, a Mahomedan, was placed under chloroform by a native lady student and died. The man, Emanbhoy Dadabhoy by name, had been admitted in the Sir Jamsetjee Jeejeebhoy Hospital suffering from disease of his upper jaw-bone. The operator was Mr. Masini, L.R.C.P. and S. Edin., the chloroformist was Miss Dadabhoy, senior student of the Grant Medical College, and the administration was supervised by Mr. B. N. Anklesaria, a graduate of the Bombay University (B.Sc. and L.M. and S.). Surgeon-Major Hatch, the senior surgeon to the hospital, superintended the proceedings, and stated in his evidence that at 8.45 A.M. he directed Miss Dadabhoy to give the chloroform, requesting Mr. Anklesaria to superintend. Chloroform was given from a linen cap, one drachm being administered at a time. One dose was inhaled for five minutes, when another drachm was poured into the cap. A third drachm was subsequently given, and after this the patient showed signs of going "over." The patient had not up to this point breathed well, so the cap was removed and held some distance from the patient's face by Mr. Anklesaria's direction. When the patient was "fairly under"—i. e., after the third drachm—he was conveyed to the operating-theatre for Mr. Masina to make an examination previously to the adoption of operative measures. Surgeon-Major Hatch then left the theatre. The chloroform was continued until six drachms had been inhaled, when, the patient being pronounced "over," the examination by introducing a director and the finger into the nostril was commenced. At the end of the examination the patient was found not to be breathing well. The chloroform was discontinued and artificial respiration commenced. All natural breathing ceased in a few seconds. Upon Surgeon-Major Hatch being fetched he found air was not entering the lungs in spite of artificial

Digitized by Google

respiration and therefore performed tracheotomy; artificial respiration was then continued for an hour. All efforts at resuscitation, however, proved futile. The lungs and heart were found to be free from disease, and Surgeon-Major Hatch expressly stated that those concerned in giving the anæsthetic were competent and had had some experience. This is one of the few deaths which have been reported from India, and unless the evidence upon which we base our report is inexact it would appear that possibly the fatality was due to an overdose of chloroform poisoning the respiratory centre. The statement made is that the death was due to failure of respiration. It may be presumed that had the impairment of respiration referred to above arisen from a hæmorrhage started by the examination of the nose or by a fragment of growth detached and fallen back upon the rima glottidis some mention would have been made of it by Surgeon-Major Hatch in his evidence. The point which is not clear is what was the interference with breathing noted as occurring almost from the commencement of the inhalation and from what cause did it arise? The culminating point seems to have been the examination of the nose, which must have caused bleeding. During the performance of artificial respiration the air did not enter the lungs. Here, again, we are left in the dark as to why any obstruction existed if the death was due simply to poisoning of the medullary centres. It would appear more in harmony with the theory that some foreign body—blood-clot—or growth had, during the digital examination of the nose, become detached and had dropped into the trachea. The method of administration appears to have been the one common in India, in which measured quantities of chloroform are poured into a linen mask or cap held over the patient's face, and the respiration is relied upon entirely for guidance as to the condition of the patient and the degree of chloroformisation. As we have said above, we can only rely upon our contemporary for the facts of the case, but trust we may receive an authoritative notice of the occurrence, and, if need be, an emendation of our account.

MADAGASCAR.

IN our notices regarding the French military expedition in Madagascar we have endeavoured to avoid all sensational statements, in view of not increasing the foreboding and depression which have generally characterised the articles that have appeared in the French press. An expeditionary force operating in a malarious climate like Madagascar is sure to have a large amount of inefficiency from sickness. That is only to be expected, and under certain conditions of season and service it may even reach a disastrous figure. This country has altogether had a pretty considerable experience of expeditions in hot and malarious climates. The amount of sickness must always be to a great extent an unknown quantity, but it will nevertheless greatly depend upon the season at which such expeditions are undertaken, the provision that is made for them, and the promptitude and efficiency with which all field arrangements—especially those of transport and commissariat—are carried out. The Ashanti War, in a most malarious and deadly climate, was a very successful expedition, because the right season was chosen and everything had, as far as possible, been provided for the troops, which care and forethought could suggest. Our first occupation of Cyprus, on the other hand, was attended with a very large amount of sickness and much mortality, because the force was sent off in a hurry at the wrong season, and, as it proved, during an exceptionally unhealthy year, without adequate provision for safeguarding their health. There was no fighting, and Cyprus has since proved a very healthy climate for troops occupying suitably selected sanitary positions. We are afraid that the last news from Madagascar must have the effect of increasing the forebodings and expressions of disappointment on the part of the French press and of embarrassing the French Government. There are said to be 5000 men of the French force sick in the various military hospitals and in the sanatorium at Nossi Komba, and the mortality since the arrival of the troops in Madagascar is said to have been very considerable. According to an account published in the *Gaulois*, "the number of dead will never be known in France." In addition to climatic fevers there has been a good deal of diarrhœa and dysentery of a malarious type. It must be remembered that exposure to freshly turned up soil is a fertile source of malarious fever, and many of the French troops have been engaged in road making. There does not seem to be any doubt that the Madagascar expedition has, moreover, been sadly mismanaged in some important particulars. We can only repeat what we have already pointed out—viz., that it is of the greatest importance to the health of the soldiers and the success of the expedition that the force should reach Antananarivo before October, when the rains set in. If the French do not succeed in doing this there is sure to be an increased amount of sickness, and the cost of the expedition, already great, will be largely augmented.

ANOMALOUS CASES OF FRIEDREICH'S ATAXY.

IN a recent number of the *Dublin Journal of Medical Science* Mr. M. J. Nolan has described three cases of this disease which present some variations from the ordinary type, especially in the association of idiocy with the physical signs of the disease. The patients are members of the same family. The parents are living, the father being, it is said, a habitual drunkard and the mother a healthy woman. There is no strong morbid taint evident in the family history. In the particular family with which we are concerned there have been eight children. Of these, the first, second, and seventh are intelligent and healthy, the fourth and sixth are dead, while the third, fifth and eighth are ataxic and idiotic. All were reared at the breast for an average period of one year and nine months. In each of the three cases of disease the signs were noticed by the mother soon after the birth of the children, and became more obvious with increasing age. The first case was that of a woman aged twenty-two who was admitted to the Down Asylum as a "dangerous idiot," she having, it was asserted, assaulted her brother. She had much difficulty in standing and walking, nystagmus was present without pupillary change, the knee-jerks were absent, and there seemed to be scattered anæsthetic patches on the skin. The breasts and genitalia were undeveloped, and there was marked interference with articulation associated with twitchings about the mouth. Athetotic movements of the arms were also present. There was no interference with the visceral functions, and no loss of control over the sphincters. There was a lateral curvature. The second case was similar in most respects, only the knee-jerks were present and exaggerated, and there was unusual development of the external genitalia. He also had the reputation of being a "dangerous idiot." The third patient was only ten years of age, and his symptoms were precisely similar. His knee-jerks were absent. These cases illustrate in most of the important symptoms the disease associated with the name of Friedreich, and even in themselves they illustrate the variability in minute points in the symptoms and signs of the disease. The important sign of the knee-jerk even varies, being present and active in one case, but absent in the two others. All of them show a peculiar mental imbecility, no doubt associated with some interference with the development of the brain, just as the physical symptoms are associated with mal-development

Digitized by Google

of the spinal cord. These cases also illustrate the varying incidence of the sclerosis in different parts of the spinal cord. In the two cases in which the knee-jerk is absent we must assume that the posterior columns are most affected, while in the other the lateral columns must be the parts most sclerosed. In a disease like Friedreich's, in which the sclerosis is usually widespread and found to affect many tracts, it is quite conceivable that such sclerosis will sometimes be greatest in the posterior columns, and sometimes greatest in the lateral, and the symptoms, more particularly the knee-jerk, will vary accordingly. The cases constitute an interesting and important addition to our knowledge of Friedreich's disease.

CATTLE DISEASES AND HUMAN HEALTH.

ALTHOUGH no very definite information was given to Admiral Field by the President of the Local Government Board in answer to his question in the House of Commons concerning the steps to be adopted so as to prevent injury to human health owing to the use of milk imported from countries where cattle disease was prevalent, yet it is a satisfaction to learn from Mr. Chaplin that he is already interesting himself in this important subject. Admiral Field's question was perhaps somewhat imperfectly worded, for it mixed up points as to milk in relation to human health—which obviously concern the Local Government Board—with others as to pleuro-pneumonia and foot-and-mouth disease, which, being diseases scheduled under the Animals' Diseases Act, concern the President of the Board of Agriculture. Indeed, the use of the milk of animals so suffering is already prohibited under an Order made by virtue of that Act; and the extent to which those diseases prevail in foreign dairies is a matter for the Agricultural Department. The question was also a little confusing in its comprehensiveness, for it dealt with all manner of infectious diseases; whereas when the Government come to deal with the subject—as, for example, on the report of the Royal Commission on Tuberculosis—the matter will necessarily have to be considered, first, as one of the spread of a bovine disease from animal to animal, and, secondly, in connexion with disease which is communicable to man by reason of food-supplies. It is this latter point, we assume, that Mr. Chaplin will take up, and to which he refers as already occupying his attention.

THE DIFFUSION OF SMALL-POX.

THERE are evidences in the records for the metropolis during last week that small-pox is not showing much disposition to decrease in London. The cases freshly coming to light in the week numbered 26, the bulk of them being ocated in sanitary areas closely bordering the River Thames both on its northern and southern banks, the north and west of London being remarkably free from the disease which clings to a well-defined group of areas in eastern London. As an example, we may state that on Tuesday of last week of the 15 cases admitted to the hospital ships all were from eastern districts. There is matter for congratulation in knowing that nearly all, if indeed not all, the attacks are promptly isolated in the ships, thus saving the metropolis from the added danger of foci of disease being maintained in populous centres. But such action is not all that is needed, for, added to this prompt removal of patients wherever possible, there should be equally prompt recourse to vaccination or revaccination of all inmates of invaded houses when these operations have not been recently or efficiently performed. Indeed, it is not too much to say that the success of the action of the health authorities to cope with small-pox must be in great measure dependent on the facilities offered to the public for securing themselves against the danger of contracting small-pox by means of exposure to the infection in houses actually invaded by the disease. It is satisfactory in this connexion to read the report which Dr. Loane has presented to the Whitechapel board of works on the measures which have been and are in operation in the district and union for securing that all the necessary measures of disinfection of premises, and of vaccination and revaccination of all persons in anywise exposed to infection, are quickly and generally carried out, thus limiting as far as can be done the chance of spread of the disease through the medium of shelters, lodging-houses, and private dwellings. Last week there were as many as six registered deaths in London in almost as many different sanitary districts, three in unvaccinated young persons and the same number in vaccinated adults. There were some 360 patients suffering from small-pox under isolation last Saturday, against 200 at the end of July. A few attacks are reported from suburban districts, but England in its southern, western, and midland counties seems free from the disease. The medical officer of West Bromwich has written to the local press contradicting the statement as to the occurrence there of several cases of small-pox last week, the borough being quite free from the disease. There is still some small amount in Lancashire towns, last week witnessing the the registration of 2 deaths in the borough of Oldham, although the cases were not in excess of that number; and Manchester again had some attacks, 3 in number, as against 6 in the Openshaw division in the preceding week. Salford had to record a single case only. In Dublin in the week ending Aug. 17th there were 3 admissions of small-pox patients to hospital, and the 1 registered death from the disease was in the person of an unvaccinated child aged under five years. The discharges numbered 4, and there were left 25 acute and 3 convalescent cases in hospital.

HOTEL SNOBBERY.

THE use of a uniform, notwithstanding certain obvious advantages conferred by it, is occasionally found by its wearer to be somewhat inconvenient. This would not be remarkable if the dress itself were designed in striking contrast with public taste or good feeling. Neither should it surprise us that the misconduct of individuals can and does bring discredit upon their cloth and all else connected with them. When, on the other hand, no ground of offence exists either in the persons or their clothes it were folly to raise objections against either. Yet this is done, and more, since instances might be cited in which, although the outward aspect has been entirely becoming and the conduct above reproach, still the sentence in some corners of society has been one of ostracism. We may quote an example of this kind which was recently noticed in the daily press. A hospital nurse, having gone to visit her father at a hotel in the West-end of London, appeared in the breakfast-room in uniform. She was there informed that she could not be admitted as a guest, as her dress was objected to. Why, we are unable to say, and we are equally at a loss to discover any reasonable excuse for a prohibition so inhospitable and so near of kin to insolence. Was the garb too plain, too work-a-day, and, if so, wherein was it a whit less neat or less reputable than that of a deaconess or a sister of mercy, or for that matter of a great many ladies not clad in uniform? Are we to suppose that the hospitality of this hotel is denied on principle to every form of dress below a certain expensive standard of quality? Perhaps, however, the nurse's costume is considered to be suggestive of morbid associations, of contagia, and the like. If this be the case, we can reassure a diffident manager and the over-nervous occupants of his establishment. No body of persons in the kingdom understand and obey more fully than do professional nurses the requirements of sanitation in regard to such matters. We hope, therefore, that neither

Digitized by Google

the pretensions of snobbish custom nor a somewhat cowardly excess of zeal for sanitation will long be suffered to curtail the just privileges of a class whose existence among us is as great a credit as a boon to society.

ST. BARTHOLOMEW'S HOSPITAL.

SOME years ago the number of surgeons at this hospital was increased from four to five, and a similar step having now been taken with regard to the physicians the newly created post was filled on Aug. 22nd by the election thereto of Dr. Lauder Brunton. This election affords a noteworthy instance of the slowness of promotion at some hospitals. Dr. Brunton has, indeed, had a long wait. He has been seeing out-patients at St. Bartholomew's Hospital for nearly a quarter of a century—i.e., for some four years as casualty physician and for twenty-one years as assistant physician. Dr. Brunton even now may in some respects be considered as fortunate to obtain the full physiciancy, for had no fifth appointment been created he would have had to wait for eight years longer, and had not a vacancy occurred owing to Dr. Southey's resignation some years ago he might never have been physician at all or have only held the post for one or two years, the age limit being sixty-four. It is quite unnecessary to dilate here on the good work which Dr. Brunton has done, since the profession is well acquainted with it, but we may congratulate both St. Bartholomew's Hospital and Dr. Brunton himself on the extended sphere of influence which is now open to him.

CREMATION IN PARIS.

THE number of incinerations called for by the representatives of deceased persons increases every year with great regularity, but the increment is so small that the partisans of cremation are well-nigh reduced to despair. According to some statistics published by the Prefect of Police the number of cremations carried out at the Père-Lachaise Cemetery from August, 1889, to the end of April, 1895, was as follows: 1889, 49; 1890, 121; 1891, 134; 1892, 159; 1893, 189; 1894, 216; and 1895 (four months), 75. The furnace would consequently often be idle were it not for the remains from the hospitals, which amount to from 2000 to 2500 bodies per annum. The apparatus employed is that of MM. Toisoul and Fradet, and works by means of gas with a recuperator. Incinerations are accomplished in an hour, or at most an hour and a quarter, and the cost of the combustible never exceeds 3 fr. per operation. Another apparatus, invented by M. Fichet, has recently been inaugurated. Like the first, it consists of a gazogene furnishing oxide of carbon and a recuperator supplying hot air to the vaulted chamber in which the reduction to ashes takes place. The difference between the two appliances lies chiefly in the application of the oxide, which is used solely for heating the recuperator, the combustion of the body being effected by hot air alone, thanks to the augmented efficiency thus obtained. According to this method incineration takes place a little more rapidly than in the Toisoul furnace, but the expense is greater by nearly a quarter, 18 hectolitres of coke being required instead of 14.

THE ETIOLOGY OF PNEUMONIA.

AN esteemed correspondent, who has, he tells us, been in practice for upwards of fifty years, thinks that the key to pneumonia, bronchitis, and other internal inflammations is not to be found in the infection by specific germs, but rather in autogenetic poisoning. He points out, for example, that pneumonia is often secondary to the specific fevers, and that bronchitis may be one of the earliest manifestations of such a fever. But apparently he thinks a greater share in the production of these inflammatory disorders is taken by depraved blood states due to defective digestion or metabolism, and affirms that the onset of pneumonia is paralleled by the equally sudden and familiar attack of arthritis characteristic of acute gout. In other words, he adopts a humoralistic pathology in contradistinction to prevalent bacteriological doctrines. In this respect he would find himself in line with those advocates of uric acid retention as the efficient cause of a vast number of internal diseases. Nor would we deny that there is much to be said in favour of such ideas, which go far towards explaining the occurrence of secondary pneumonia, pericarditis and the like. On the other hand the adoption of the belief in the necessity of external infection would relegate all these blood states to the region of secondary rather than essential causes. It is not difficult to conceive that, given certain states of nutrition or rather denutrition, the tissues are rendered more prone to attack by specific agencies such as the pneumococcus.

THE INTERNATIONAL CONGRESS OF OTOLOGY.

THE fifth of these gatherings will be held in Florence from the 23rd to the 28th of next month, under the presidency of Professor Grazzi. We have already published the subjects which have been selected for general discussion, to be introduced by Dr. Barr (Glagow), Dr. Gellé (Paris), Professor Gradenigo (Turin), Professor Politzer (Vienna), and Dr. Secchi (Bologna). The complete programme has just been issued containing the titles of fifty-nine original communications. The social aspect of the meeting has already been well provided for by private and public banquets, a concert at the Artists' Club, a reception within the classic walls of the Palazzo Vecchio, and an excursion to Fiesole. The comfort of visitors has been further assured by arranging with several of the leading hotels for bedroom service, lights, attendance, and morning coffee for the very reasonable price of from 3 fr. to 5 fr. All the Italian railway companies have granted reductions of from 30 to 50 per cent. to those attending the meeting, available from Sept. 12th to Oct. 8th. The arrangements in connexion with the various routes and fares made by Messrs. Cook and Son will be found in another column of our present issue. The Congress promises from every point of view to be a most interesting success, and will afford to its members a pleasant opportunity of seeing the Tuscan capital under most favourable circumstances. It is hoped that British otology will be well represented, as it has been decided to invite the sixth Congress to meet in London either in 1898 or 1899. The subscription is 20 francs (16*s.*), and entitles the *Congressista* to a copy of the printed transactions. This can be paid to Dr. St. Clair Thomson, 28, Queen Anne-street, W., from whom vouchers and all particulars as to routes, hotels, &c., can be obtained.

IS HELION IN THE AIR?

IT would appear that helion—that element supposed hitherto to exist only in the sun—has been found in the air. If this be so, then the theory that it has been found on earth only in certain minerals because these have locked it up and brought it to earth from the sun's atmosphere must soon totter. Associated in small quantities with argon, which in turn occurred with its apparently inseparable companion nitrogen, helion has been found issuing as a "stream into the air" in the gases of the springs of Wildbad in the Black Forest. Hence, concludes Professor H. Kayser of Bonn, to whom the discovery is due, free helion must be found in the air along with argon. We do not quite follow this line of argument, however, since many parts of the world, amongst which our own country may be reckoned, are not favoured with fissures

Digitized by Google

in the earth or with springs which are constantly pouring a stream of "argoniferous" gas into the air. The spectroscopic lines, he adds, are certainly very faint, but distinct enough for him to consider the presence of helion in the air of Bonn as being beyond any doubt. We believe, on the information of Professor Ramsay himself, who discovered helion, that the most searching attempts to demonstrate the existence of helion as a normal constituent of the air, or at any rate that sweeping across the British Isles, failed entirely, so that if it is about to be shown on the lines recently announced by Professor Kayser that the atmosphere is here with and there without a constituent we may hope possibly for some explanation of the beneficial effect derived from "a change of air." The observation may possibly throw some light, too, upon the value of "taking the waters," since obviously where springs abound, and especially effervescing springs, there is a greater chance of helion, as well as argon, being present. In the face of these developments we are constrained to repeat what we said in a leading article on argon and helion in THE LANCET of May 25th, 1895, that the real importance of the joint discovery of Lord Rayleigh and Professor Ramsay is yet to be estimated.

THE GRIEVANCES OF THE TELEGRAPH SERVICE CLERKS.

A COMMITTEE of inquiry which is now sitting to investigate the grievances of the telegraph service clerks has recently received evidence intended to show that the monotonous and exacting nature of telegraph instrumental work has a seriously damaging effect upon the health of the persons engaged in carrying it on. We have ourselves remarked in former times upon the trying character of such work when performed under the conditions of continuous pressure and prolonged hours, and we should have been fully prepared to find that the conclusions to which theoretical considerations point would be supported by statistics drawn from the experience of the department in dealing with the very large staff employed about its work; but for some reason which we do not understand the statistical evidence does not seem to have been forthcoming. It appears that some years ago the causes of retirement from active service and of death were given with some exactitude in an annual return to Parliament, and that the evidence thus afforded of excessive nervous strain was such as to call for special comment at the time. If it be a fact that the publication of these details was discontinued because of those comments then we think that such conduct on the part of the authorities cannot be too strongly reprobated; but, although a charge of that sort is distinctly hinted at, it is not in any sense proved, and it is therefore proper that we should refrain at present from doing more than to draw attention to the suggestion made, and add a suggestion that it might be wise and even proper in future returns to give the fullest possible information concerning the maladies from which members of the telegraph service are shown to suffer. For want of better material the spokesman on this subject of the telegraphists quoted some statistics drawn from the last published report of the United Kingdom Postal and Telegraph Service Benevolent Society. If these figures could be relied upon they would make a very strong case, but we fear that they cannot be accepted with any confidence. According to our information the Benevolent Society receives all comers without discrimination provided they be members of the service which is to be benefited by the society's operations. Now, if that be so, its membership is, of course, much more attractive to damaged than to sound lives, and the society will, therefore, suffer from an adverse selection of risks, and its experience cannot be expected to be typical of that of the service at [illegible]. If these are the best available figures the fact is [illegible]retted, for best or worst they are really *nihil ad rem*. But it would seem, from some suggestions made by Mr. Spencer Walpole, that better statistics are accessible. If so, we hope that they will be laid before the committee, for the point is one of vital importance to a large and meritorious body of public servants and of no small interest from the medical point of view.

DIPHTHERIA IN LONDON.

HIGH as was the average of the weekly number of deaths registered in London in the four weeks of the present month, ended last Saturday—namely, 46—it has been exceeded in all but one, the respective registrations of fatal cases having been 57, or 23 above the corrected decennial average for the corresponding week; 55, or 23 above the corrected average; 50, or 19 above that average; and last week only 24, or 7 below the average. Thus, although last week witnessed a fall as compared with those preceding, there is no cause for congratulation in this constant overtopping of averages. Allocating the deaths in the four weeks in question to the sanitary areas furnishing multiple fatal cases, the Registrar-General states that in one of the weeks there were 4 each in Chelsea, Paddington, and Mile End, and 6 in Camberwell; in a fortnight 7 each in Bethnal-green and St. Pancras, and 8 in Kensington; and in three weeks 15 in Poplar; Islington figuring in all four weeks with a total of 16 deaths. As regards the number of cases, the records show that in the four weeks just named the cases coming to light were upwards of 800 in total against a total of over 1000 for the like period immediately precedent. But the records show with reference to cases no sufficient warrant for regarding the disease to be much on the wane at present if we have regard to individual recent weeks, last week among them. Taking these four-weekly totals of attacks and the totals of deaths for like periods, it is seen that whereas in the earlier of the two the per case mortality was 17 per cent., in the latter period it was 23 per cent. In Greater London, in the last four weeks, the deaths from diphtheria have been respectively 11, 7, 19, and 5, and of this total of 42 no fewer than 19 are credited to the West Ham district. Last Saturday the patients remaining under treatment in hospital in London numbered 666, having been upwards of 600 in number for many weeks, and having been 681, 686, 689, and 657 in the four weeks immediately preceding.

HONORARY HOSPITAL APPOINTMENTS.

LAST week the appointment of an honorary medical officer to the Royal Albert Edward Infirmary, Wigan, once more showed the humiliating, and we might say the degrading, resources which medical men are subject to for the sake of obtaining an appointment which is unpaid. Almost before the late medical officer was carried to his last resting-place canvassing was commenced, and has been prosecuted with great energy during the last six weeks. We believe that only two out of the six candidates failed to personally canvass. We are pleased to say that one of these gentlemen for his courage came in a good second in the race though he did not quite win. The voting was by ballot and after the manner of a Parliamentary election, the Mayor acting as returning officer; circulars and cards were freely sent, and as many proxies as possible were obtained. At the meeting which was held for the purpose the chairman of the board of management mentioned that it had been suggested that this mode of election should be done away with, and that instead an election committee should be formed consisting of the members of the board of management (which has four members of the medical board in its composition) and a given number of representatives of the donors and governors elected at the annual

Digitized by Google

meeting for the purpose; this plan did not meet with the approval of those present. They think, it would appear, that if the mode of election were altered they would be deprived of something which they possess. The representatives of works appear to value the privilege of voting; so much so, that one gentleman gave his proxy for one candidate and then voted for another by ballot. The hospital authorities think that an election like this does them good, reminding subscribers to pay up their subscriptions, and that it also increases the number of subscribers. They might, however, remove a portion of the degradation by making a personal canvass a disqualification.

A SUSPECTED CASE OF CHOLERA.

A CASE exhibiting at first sight some suspicious features has occurred in Wandsworth. The patient was a man named Hancock employed in collecting waste fat &c. On the morning of the 24th he was taken ill with acute diarrhœa and abdominal pain. For some three days previously he had complained of slight diarrhœa, but had continued at his work until Friday, the 23rd. Vomiting commenced on Saturday evening. On Sunday, the 25th, he was worse, and a medical man was called in. The stools were copious, watery, with a few flocculi, but bile-stained. The vomiting was constant, and in the evening he was said to have passed a little urine. The symptoms continued on Monday, with the addition of cramps, and at 7 P.M. a catheter was passed but no urine was found. He died between 9 and 10 P.M. Post mortem nothing definite was found except some slight congestion of the lower part of the ileum and the ascending colon. There was no evidence of obstruction or strangulation. In view of the symptoms during life, portions of the bowels were sent to Dr. Klein for bacteriological examination. As the result of his investigation it has been decided that the case was not one of the true or Asiatic disease. It was probably one of acute diarrhœa, brought on by the unsavoury nature of the patient's occupation.

THE Students' Number of THE LANCET will be published on Sept. 7th, and will be found to comprise every information for those intending to enter the medical profession.

DR. ALBERT GUNTHER, F.R.S., the keeper of Zoology at the Natural History Museum at South Kensington, has resigned his post after having held it for over thirty years.

MR. R. B. FINLAY, Q.C., the newly appointed Solicitor-General, was originally educated as a medical man, and obtained the degree of M.D. Edin.

MEDICINE IN THE SPANISH PROVINCES.

(FROM A CORRESPONDENT.)

AFTER several years' residence in Spain it has occurred to me that English medical practitioners might feel some interest in comparing the present state of their profession in that country with that depicted by the incomparable Gil Blas when he described his stay with Dr. Sangrado. It might cause them to be surprised—nay, incredulous—were they told that one at least of that worthy physician's great remedies—bleeding—is still in vogue among a few of the older school, with whom even the pungent satire in that work of disputed parentage has proved ineffectual. The capitals and larger towns of Europe are fast assuming such a cosmopolitan character that they cease to represent the average advance of any one nation in the march of civilisation, but give one rather the result of a few isolated and more or less successful attempts in that direction. For the purpose, therefore, of this article I have eliminated Madrid and the larger towns of Spain, though at some future time I may perhaps have some words to say about the capital and its magnificent water-supply. In the smaller towns, however, one sees the "medico" as he is—that is, the average practitioner, the rank and file of the profession—some content to do their work in a perfunctory sort of way, others wearing out their energies in an attempted struggle against the mass of ignorance and prejudice that everywhere surrounds them. The system that prevails in Spanish provincial practice is the *iguala*. This is, for all intents and purposes, the same as the club system. Most inhabitants of a town or village pay a yearly subscription for themselves and for each member of their family, entitling them during that period to free medical attendance. Midwifery, surgery, and night cases are alone excepted. Though this has the advantage of enabling a practitioner to gauge his income fairly accurately, it has the disadvantage of placing him at the mercy of cabals. Intellectually the "medico" is the leader of his little world. Should there, however, be any member of the legal profession in the village he would divide the honours with him. The *cura* (priest) may or may not arrive at his intellectual level, whilst the same may be said of the schoolmaster, who is considered a person of such small consequence that they often neglect to pay his salary for periods ranging from six months to three years. As a natural result he has to live on credit during that time, but as protracted credit is often little better than begging on one side and alms on the other this much ill-used class finds it hard to retain its self-respect and authority. So much for intellect.

We now come to the *caciqués*, who really are the influential class. These are the moneyed and landed individuals, employing a great deal of labour and often, unfortunately, increasing their wealth and power by resorting to usury. Being, however, for the most part men of but slight attainments, it is scarcely to be wondered at that they should strive hard to make use of the intellect around them to their own particular advancement. With the advent of the elections a medical man's troubles begin. At the commencement of his hospital walking he may have taken a languid interest in politics, or if of an enthusiastic and restless disposition may have had temporary leanings towards Republican ideals. Once in possession of his practice his political tendencies will have grown cold and he probably looks on polemics and parties with that supreme indifference and superior contempt which most educated Spaniards feel in their hearts.

It may seem a sweeping statement to make and one that will surprise Englishmen, but few intelligent Spaniards have any political faith. Most make use of a party, but centuries of bad government have destroyed all hope of its doing anything really useful. There is a legend which the Spaniards tell that the Virgin Mary asked her Son for various favours for Spain, such as sunny skies and a beautiful climate, and that then she asked as a last favour for good government, but that this was not granted on the grounds that such a measure would convert Spain into Paradise. With no definite political tendencies, therefore, it becomes evident that interest remains the only factor in the selection of a party, and most "medicos" adopt this plan and join the forces of the strongest *caciqué*, who, in his turn, uses his influence in favour of the candidate or the party that he thinks will be of the greatest assistance to himself. However, the followers of the opposite party in the village will never forgive the medical man for not joining their own ranks, and if strong enough will send for another practitioner, to whom they will in due course pay their *iguala*. Through these causes I have known three medical men established in a small town on terms of the most cordial enmity where one practitioner would have sufficed. Abstention from voting does not benefit him, as all parties would have a grievance, and their defection would leave him without a patient and, what is worse, without his fee. However, this is not a political article, and I will now proceed to consider the position of a Spanish provincial medical man in its other aspects. Socially considered, it might well admit of improvement. The absence of that class of small landed proprietors who live mostly on their estates and the concentration of the land into immense properties in the hands of a few wealthy owners, with whom absenteeism is the rule, only varied by

Digitized by Google

flying visits every year or two, are amongst the chief reasons accountable for the slow progress of civilisation in the provinces of Spain. A notable exception, however, may be found in some of the northern provinces, such as Galicia, where the more equable distribution of land tends to produce not only greater personal freedom, coupled with more satisfactory social intercourse, but also a much higher intellectual average. It therefore follows that in most of the provinces the medical man has to fall back upon one or two equals in education in the villages and perhaps half a dozen to ten in the more important townships, and of these probably half are, through no desire of his own, political adversaries and therefore just barely civil. It is hardly to be wondered at, then, if in the course of years he drifts down to the intellectual level of his patients, loses the enthusiasm of early days, gradually forgets what he knew, and gets completely behind the age.

In my introductory remarks I have referred to bleeding as being still practised in Spain. It is only fair, however, to say that the present generation of medical men there are in every way equal to the average practitioners of other countries and have set their faces against this practice, which, by some of the older men, is still considered the panacea for all the ills that flesh is heir to. I have known a patient insist on being bled by his medical attendant, who, however, only complied under protest and in the conviction that a little judicious blood-letting by himself would be preferable to handing his patient over to the village barber, whose discretion in the matter might not be so great. This worthy is a recognised though uncertified minor surgeon. Besides his razors, brushes, and scissors he provides himself with lancet, leeches, corn knife, and a variety of surgical and dental instruments. Occasionally, also, he does a little bone-setting, though this is, strictly speaking, within the province of the *curandero*, or bone-setter, to whom I shall shortly refer. On the barber's shelves may sometimes be found a work on anatomy and occasionally a treatise on the virtues of herbs in the cure of ailments. His lack, however, of a good elementary education, to say nothing of the rudiments of medical science, renders these works worse than useless to him, except inasmuch as they enable him to secure a good vocabulary of technical phrases, which, however misapplied to the case in point, have the desired effect of confusing and impressing his already too credulous patrons.

Whilst being shaved in a small town I have had some startlingly new ideas propounded on the theory and practice of medicine. I am afraid, however, that they produced more amusement than instruction, and though careful not to contradict one who, with a razor to my throat, might justly be considered the arbiter of my destiny, I can hardly refrain from hoping that the practice thereof may be strictly confined to the confiding patrons of each village Figaro. The art and mysteries of a *curandero* are handed down from father to son. He devotes himself to setting bones and repairing injuries generally, and his attentions are not confined to man, his field of operations extending to all such members of the animal world as have a master willing to pay the recognised fee, and on the whole his work seems to be fairly well done. Attempts have at various times been made to suppress *curanderos*, but the *vox populi* is with them, and thus far they have been able to maintain their own even in some of the larger towns. I have heard of a noble family sending miles for a celebrated *curandero* when they had the services of two really good surgeons within easy reach. The reasons for their continued prestige are complex and somewhat curious. In the first place, the bone-setter has generally a town and some four to six villages as his field of operations, and in each he, with characteristic modesty, details the marvellous cures he has achieved in the others; secondly, the medical man is an accepted fact, his remedies are supposed to be known quantities, and a knowledge of them open to all who may have the inclination or the means to study them. With the *curandero*, on the other hand, things are differently viewed. His art is a secret one possessed by few, and is looked upon as something like a special gift from Heaven, on the principle of *Omne ignotum pro mirabile*. If we add to this the fact that he has, as a rule, the simpler cases to deal with, and can therefore often show a greater percentage of cures than the certified surgeon, who would be invariably called in to attend a badly fractured limb, it becomes easier to understand how it is that bone-setters still flourish in a country too long deprived of just educational facilities.

NOTES FROM SINGAPORE.

(FROM A CORRESPONDENT.)

The Influenza Epidemic.

THE influenza epidemic of 1895 has not been limited to the "home" countries. During the past three months the Straits Settlements and the adjoining native states have suffered severely from this well-known scourge. The general characteristics of the disease have in no way differed from those which have been noted in Europe. The native Malay, the Eurasian, the immigrant European, Chinaman, Indian, and Arab have all fallen victims to the disease. Amongst Europeans severe or fatal cases have been rare, but the death-rate in the case of Asiatics has been exceptionally high. We have seen the gastro-intestinal, the cerebro-spinal, and the pulmonary forms in great frequency, the last being by far the most common. Pneumonia, broncho-pneumonia, and other forms of pulmonary affections have carried off many of the natives. In a large proportion of these cases the duration of sickness was extremely short. Heart complications have been far from uncommon, and the writer of these notes has met with at least a dozen well-marked examples. The majority have shown acute dilatation of the left ventricle, slow pulse or else a very rapid and feeble one, with frequent irregularity in rhythm, and death from cardiac asthenia in from twenty-four to forty-eight hours. When life in these cases is prolonged various murmurs are to be noted, chief among which are those showing mitral and aortic insufficiency. Irregularity of pulse has persisted in some cases for months after the initial attack, and attacks of angina are frequently met with. As at home, patients who already suffer from heart disease stand a bad chance when struck down by "the grip," and die from cardiac syncope or from a low form of pneumonia. More especially is this the case in beri-beri, for in patients suffering from this disease influenza is exceedingly fatal. When "the grip" occurs in an acute attack little else than cardiac collapse, without appreciable fever or the characteristic pains, the resemblance to an acute attack of beri-beri is most marked. This resemblance is rendered greater in cases, two of which came under my notice, where peripheral neuritis follows close upon influenza as a complication. Both of my cases made perfect recoveries, although one was accompanied by dilatation of the ventricles. Malaria as a sequela has been frequently noted, and in a few cases has been fatal. Amongst Europeans especially I have seen a number of cases of acute phthisis arising as a rule out of unresolved pneumonia, and in these a fatal termination usually ensues in one or two months. Some cases linger on, however, for a longer period. Finally, although I have not the exact figures before me, the death-rate during the last two months or more has greatly exceeded that for the corresponding months of last year.

Epidemic Asiatic Cholera.

Unfortunately, influenza has not been the sole cause of our present high rate of mortality. Asiatic cholera in an epidemic form is a rarity in Singapore, and we have hitherto congratulated ourselves on our immunity from its ravages. Our excellent municipal water-supply has been long held up as the main agent in preventing epidemics of cholera, but that a good water-supply is not a *sine quâ non* in this respect has now been demonstrated to us in a very emphatic manner. Other factors have been at play, such as back-to-back houses, overcrowding, want of proper drainage, and the filthy habits which are a characteristic of most Asiatics. These have finally led to consequences which were sooner or later inevitable. At a meeting of the Municipal Commission on June 19th the medical officer of health, Dr. Middleton, stated that "the death-rate began to rise about the beginning of April, but no cases of cholera were reported. Still it was suspected that there was some epidemic going about the town, though they were unable to get hold of it. Since then, during the last week, the death-rate had risen to 75 per 1000. The first indication of cholera they had was on Monday, the 10th of this month [June], and since then forty cases had been reported, of which thirty-six had proved fatal. ..... There was considerable difficulty in dealing with these cases, because the Chinese and natives concealed them in order to prevent patients being sent to hospital, nor were they usually called in until after death had taken place." The means adopted to check the spread of the disease are, in

Digitized by Google

Dr. Middleton's own words, these: "Whenever a case was discovered the man was sent to hospital at once, his mats and bedding burnt, and his drinking vessels broken, compensation being given where such articles were destroyed." In all cases, too, the infected house is thoroughly cleansed and disinfected by the municipal authorities.

The Government and the Municipality.

The following letter, received by the President of the Municipal Commission from the Colonial Secretary, was read at a meeting of the Commission on June 19th:—

"Colonial Secretary's Office, Singapore, June 14th, 1895.

"SIR,—I am directed by the Governor to direct the attention of the Commissioners to the exceptionally high death-rate in Singapore for the month of April last, as shown in the Registrar-General's return, a copy of which was sent to you on the 1st inst. (2) It will be seen that the number of deaths in that month recorded was no less than 770, as compared with 477 in the corresponding month of last year, and exceeded by 172 the highest number previously recorded for the month of April during the last ten years. (3) His Excellency is of opinion that the abnormal figures appear to indicate the prevalence in Singapore during the month referred to of some cause of death intentionally or carelessly kept back by the natives from fear of consequences which might result if it were reported, and I am to request that the Commissioners will give their consideration to a matter which would appear at first sight to indicate that much closer attention and supervision on the part of their medical officer may be desirable.

"I have, &c.,

"J. A. SWETTENHAM, Colonial Secretary."

The irony of this letter is evident when one notes that the death return for April was delivered by the Government to the municipal authorities so late as June 1st, that this was the first official indication to the medical officer of health that the death-rate in April was so unusually high, and that the entire onus of such a lax state of affairs rests with the Government by reason of the present erroneous and inefficient system of death registration. Such a wanton censure of an able and energetic medical officer, such an attempt on the part of the Government to make the Municipal Commission a scapegoat for its failings, have led to universal expressions of indignation from the public of Singapore, who now call emphatically for an immediate and radical change in the methods by which vital statistics are at present obtained.

The Present System of Registration of Deaths in the Colony.

The present law makes it the duty of the occupier of a house, in which a death happens to take place, to notify the death within twenty-four hours to the deputy registrar of the district, who is in all cases a police-constable. These are usually Malays or Tamils. Failing a medical certificate, the constable fills up a form and states the cause of death, either following the notifier's statements or giving his own diagnosis from inspection of the corpse or otherwise. In many cases, as was described by Dr. Dumbleton, a retired municipal medical officer, in a paper read before the Straits Medical Association, a medical certificate is by no means a guarantee of correct registration, but is often altered according to the fancy of the deputy registrar. These registers, usually made out in Tamil or Malay, are translated into English at the end of the month and are then forwarded to the Registrar-General. The latter tabulates them, and finally, well on in the following month—in the specific case referred to in the Colonial Secretary's letter fully a month later—they are transmitted to the municipal medical officer. In this way this official is kept in total ignorance of the death-rate in the district which is his special care, and he can have no guide or indication which might lead him to suspect the presence of any unusual fatal element until some weeks later. It might be argued that the Infectious Diseases Notification Act is a help to him in this direction, but the present epidemic shows the fallacy of this. Almost all the cases have occurred amongst the poorest class of natives, who either do not by preference or cannot afford to call in European general practitioners. That the system calls for immediate alteration at the hands of the Government must be evident to everyone who has the welfare of the Settlement at heart. Deputy registrars should be no longer ignorant police-constables. The posts should either be given to trained apothecaries or something akin to the parochial system should be instituted, so that, failing a certificate from the deceased's medical attendant, a proper medical certificate may in all cases be obtained. All such certificates, too, should be made out in duplicate, one copy going to the medical officer of health within twenty-four hours of the death and the other being sent, as heretofore, to the Registrar-General.

SLAVERY IN ZANZIBAR AND PEMBA.

ZANZIBAR has for many years been known to the public as the starting point of exploring expeditions about to enter Equatorial Africa from the eastern side, and the recent extension of a British Protectorate over the territories of its ruler causes us to regard it with an increased feeling of interest and responsibility. The upper classes are Mohammedan Arabs; they have been slave-traders and slave-owners from time immemorial, and a special investigation of the condition of the negroes has just been made at the instance of the British and Foreign Anti-Slavery Society. The society's commissioner, Mr. Donald Mackenzie, is acquainted with the Arabic language and has had long experience of Mohammedan customs and slavery among the Arabs in North-West Africa. He arrived in Zanzibar on March 2nd, 1895, and devoted about six weeks to his inquiry. The territories of Zanzibar consist of the coral islands of Zanzibar and Pemba, lying about twenty-two miles apart, between 5° and 7° S. latitude; the former island is less than twenty-five and the latter less than thirty-five miles from the African mainland. There are no precise data as to the population, but the late Sultan, who died in 1888, estimated the inhabitants of the two islands at 400,000, of whom 200 were Europeans (merchants) and Goanese (shopkeepers and servants), 8500 were natives of British India (moneylenders and merchants), 10,000 or 15,000 were Arabs (the ruling class), 266,000 were slaves, and the balance were aborigines and slaves who had been set free. The slaves may be classified as domestics (including concubines and eunuchs), plantation workers, chiefly occupied in the cultivation of cloves, and town labourers. These last work under entirely different conditions from the domestic and plantation slaves. They are employed: (1) in the loading and discharging of vessels and in general warehouse and town labour, women being largely engaged in this work and especially in the coaling of steamers, including British men-of-war; (2) as porters who carry goods or stores into the interior of Africa; and (3) as domestic servants to Europeans, natives of British India, and Goanese, who not being themselves allowed to possess slaves have to hire them from their owners. All British subjects deal with the slaves directly and not with the master, or they may hire them from a contractor, who need not necessarily be a slaveholder, but who knows where to get them. Employers pay wages to the slaves, who, in turn, hand to their masters half of their earnings, and with the remainder have to buy their own food and clothes: in the case of porters the hirer has to provide them with food. The pay of porters and harbour labourers is usually ten rupees per month; women labourers receive less. The regulation load of porters is 70 lb. each, but beyond that they have to carry food, water, and cooking utensils, which may bring the load up to 100 lb. or more. They have to march about twelve miles a day. These slave porters are the only means of transport for our Government and for missionaries and merchants between the interior of Africa and the coast. If any of them are taken ill they are left by the path-side to die, their loads are distributed among the others, and the caravan proceeds on its march without any further notice being taken of those who drop by the way. The mortality amongst them was given to Mr. Mackenzie on the very highest authority at 30 per cent. Domestic servants are generally men, and they receive about seven rupees per month; the women are water-carriers and are paid five rupees per month. They all receive their wages directly from their employers, but each hands to the master one-half. A slave is told by his master to seek employment, and if he cannot find it he is punished. The masters have hardly any responsibility as regards the slaves and only provide them with food when they are out of employment. None of the slaves possess any civil rights except that they can complain against their masters to the British Consul-General, but at present very few know of the Consul-General, and under existing circumstances freedom would be no benefit to them, for they would be outcasts, and their masters would have many ways of getting rid of them by poison and otherwise. Many of the slaves who have been set free by the Consul-General have afterwards been kidnapped and all trace of them has been lost. Mr. Mackenzie was much impressed by the fact that very few children are born to slaves, owing, it is said, to the manner in which very young girls are treated

Digitized by Google

by the Arabs and others; hence the necessity for continued importation from Africa to keep up the number. Taking the death-rate at 30 per 1000, upwards of 7000 slaves would have to be imported annually. He is of opinion that some 6000 are imported yearly into Zanzibar and Pemba from the mainland, not in dhows, which attract too much attention, but in sailing canoes, of which there are upwards of 2000 in Zanzibar and quite as many in Pemba. The export of slaves to the Arabian coast from the mainland of East Africa is probably some 11,000 per annum. About 1500 dhows are known to make two voyages a year, one to Zanzibar and East Africa and the other back to Arabia in the south-west monsoon; each of these vessels takes on an average seven slaves, though some may carry a larger number. According to the report of the Select Committee on the East African Slave Trade, presented to Parliament in 1871, the export from the mainland into Zanzibar and the Arabian coast amounted to upwards of 20,000 slaves per annum. In nearly all the dhows which have been captured going north in these parts from time to time small boys were found mutilated for eunuchs for the harems in Arabia. These boys are operated upon by native doctors, and the mortality is reported to be very great. The Sultan of Zanzibar is said to have fifteen eunuchs to guard his harem, but it does not appear that any other Arabs have them in these islands. The Sultan is the principal slaveholder, being supposed to own 30,000 slaves. Of his subjects, one has six *shambas* or estates, with 3000 slaves on each, and another has seven *shambas* and 10,000 slaves.

Mr. Mackenzie gratefully acknowledges the assistance and information he received from Mr. Hardinge, the British Agent and Consul-General, Sir Lloyd Matthews, the Prime Minister of the Zanzibar Government, Archdeacon Jones-Bateman, and others. He is convinced that the legal status of slavery should be abolished as soon as possible, although the majority of the European residents are in favour of its retention on economic and utilitarian grounds. He has also given an interesting account of his visit to the island of Pemba, where he spent several days, being, as he understands, the first European to explore it.

THE BATTLE OF THE CLUBS AT BRUSSELS.

(FROM OUR SPECIAL COMMISSIONER.)

THE cause which led to the resignation of the twenty medical men who were engaged in the service of the Federation of Mutualist (or benefit) Societies at Brussels has been fully explained.[1] There are, however, lessons to be derived from this struggle which are worth noting. First and foremost stands the fact that at Brussels, as at Cork, the great mass of the working population at once took sides against the medical men. Undoubtedly, and this has been demonstrated over and over again, it is doubly difficult to bring such a movement to a successful issue unless popular sympathies are enlisted. The first care, therefore, that medical men should take is to put themselves right with the public. The great blunder committed at Brussels has been the omission of this precaution. The Medical Syndicate has negotiated with the committee of the Mutualist Federation, as if these two bodies alone were concerned. The consequence is that a quarrel has broken out in which some 50,000 persons are materially concerned, and not one in a hundred knows what it is all about. Yet it was all the more necessary that the Medical Syndicate should appeal to the rank and file of the Mutualist societies, as the committee representing the federation of these societies is composed in the main of precisely the element most affected by the action of the medical men. What can be said of Brussels will be found to hold good very generally in England. The majority of members of such clubs or benefit societies are workmen or others whom the medical profession are very willing to attend at low contract rates because they are too poor to pay proper fees. But there is also, though in much smaller numbers, a middle-class or well-to-do element which the medical profession rightly consider should be excluded from such benefits. Now, it is precisely this well-to-do, middle-class element which, by reason of its superior education and ability, supplies a very large portion of the members of committees, managers, secretaries, &c. of the clubs. Thus medical men sometimes find themselves obliged to propose the exclusion from medical benefits of the very members of the committees with whom they have to negotiate. Under such circumstances it will be seen how very important it is to appeal from the committees to the constituencies. This is all the more necessary as what the medical men desire is really to the interest of the poor members of benefit clubs. Great care should be taken to point out that comparatively rich persons are unjustifiably trespassing on the time medical men should devote exclusively to the poor. How thoroughly the whole state of the case was misunderstood by the rank and file of the benefit clubs of Brussels I had an excellent opportunity of estimating.

A general meeting of Mutualists was convoked at the Alhambra, one of the largest theatres of Brussels. Though I arrived in good time, and the theatre is said to hold some 5000 persons, I found that the police had already closed the doors, the crowd being so large that an accident was feared. It was with the greatest difficulty, and as a special privilege to the press, that I obtained admittance and standing room to witness the proceedings. The speeches, delivered for the most part by members of the committee of the Mutualist Federation, represented the medical profession as actuated by the most sordid motives. The medical men, the public were told, wished to institute an inquisition so as to ascertain the precise state of every member's fortune. Each member of a benefit society would in future have to be provided with a diploma of indigence. It was an insult to thus qualify them all as paupers. They were not paupers, but prudent men who took out an insurance against possible sickness. It was not because a few persons had attained easy circumstances that the advantages of benefit clubs should be withdrawn from the others. One speaker had joined when he was earning as a clerk £64. He was then able to save enough on this to buy a gold chain for his watch. Now he was earning £180; but, as a husband and father of a family, he found himself so much poorer that any purchase of luxuries was quite out of the question. He felt that with the larger income he was more entitled to join a benefit society than with the smaller income. Another speaker said that benefit clubs were as commercial travellers working on behalf of medical men. They took the young, unknown practitioner, perhaps they did not pay him much, but they made his reputation and created his practice. Medical men were roundly abused by several speakers. Some were described as riding about in luxurious carriages and refusing to put their science at the service of the poor; but they utilised the poor as a mere field for experiments. Then we were led to infer that there was a nice little piece of jobbery going on between the Medical Syndicate and the dispensing druggists. An alliance had been formed between the medical men and the druggists to crush out of existence the "popular pharmacies"; and, if this was successful, it would be the death warrant of all coöperative societies and enterprise.

This was a very effective thing to say, as the whole of the Belgian labour movement derives its strength from vast coöperative productive and distributive societies that pay no dividend, but employ the profits to reduce the sale price and for purposes of political propaganda. This argument was, therefore, a distinct bid for the support of the Belgian Labour Party, which has returned thirty out of the 150 deputies that constitute the Belgian Parliament. It might be inferred that the popular pharmacies are coöperative institutions similar to those founded by the Labour Party; this, however, is not at all the case. The popular pharmacies were started some time ago by an individual, and as a speculation. This individual went the round of the benefit societies, offered to give them a large financial interest in his business if they would reserve their custom to his pharmacies and give him a certain sum to form what he called a guarantee fund. By means of this fund he got the capital for his business and assured himself of the custom of the benefit societies. Nine such so-called popular pharmacies were opened in different parts of Brussels. Of course, when it was seen that the mutualists all went to these popular pharmacies the general public also patronised these establishments, being under the impression that the medicaments were sold at a much cheaper rate. Thus an enormous trade has

[1] THE LANCET, Aug. 24th, 1895, p. 476.

Digitized by Google

been done, and the benefit societies got back as their share of the profits a large amount of the money they spent in drugs. I have seen the accounts of one society which paid in the course of last year 13,195 francs for drugs to the popular pharmacies, but got back as its share of profits for the same year 9987 francs! Naturally these profits were made in the main, not out of the members of the benefit societies, but out of the general public, and this of course greatly to the detriment of the ordinary druggists. So keen is this grievance that a law has been passed in the Belgian Parliament, and will come into force next year, by which societies of this description shall be allowed to sell only to their own members and not to the general public. It seems, therefore, that if there is any jobbery at all with regard to the dispensing of medicaments to members of benefit societies, it rests with those benefit societies themselves rather than with the medical profession. The medical men do, however, urge that it is very awkward for so large a town as Brussels to have only nine pharmacies where the members of the societies can get their medicaments. This is the greater inconvenience as, though they often have to go very far for the drugs, they do not get them any cheaper. On the contrary, the 180 dispensing druggists of Brussels have agreed to charge all members of the Federation of Benefit Societies only half what they are in the habit of paying at the popular pharmacies. By this arrangement the rank and file of the benefit societies could go to the nearest druggist or to any druggist for whom they might have a preference. This would be much more convenient and cheaper, but it would put an end to the profits which the benefit societies derive from trading with the general public.

There was one feature in the meeting by which I was greatly impressed. Nearly all the speakers used against the Medical Syndicate the usual arguments brought to bear against trades-unions when there is a strike. Strange to say, the working men who composed a large section of the audience were trades-unionists and must themselves have been on strike many a time, utterly failed to recognise that they were combating the medical men with identically the same arguments which had been employed against them when they as workmen strove for higher wages or shorter hours. For instance, a letter was read from the secretary of the Medical Syndicate, couched in strong language and pointing out to some medical man the consequences that would accrue if he worked for the Mutualist Federation against the interests of his own profession. It was just such a letter as the secretary of a trades-union would write to a "blackleg" during a strike. One would have expected the working men present to have recognised the tone at once and to have applauded its contents; but, on the contrary, they allowed a speaker to invoke the law in favour of the "liberty to work" by which "blacklegs" are protected against strikers, and to declare that no society will submit to the tyranny of a medical syndicate, just in the same language as employers declare that they will not submit to the tyranny of a trades-union. It was extraordinary to note how quickly working men, who were for the moment in the position of employers, at once adopted the tone, the language, and the arguments of the capitalist fighting against the claims of labour, and, furthermore, unanimously voted in favour of a resolution to that effect.

This state of feeling must be reckoned with; and wherever such a struggle breaks out it must be checked or altogether prevented. That it arose at all is due to the fact that the Medical Syndicate limited its efforts to negotiations with the middle-class committeemen of the Mutualist Federation and either did not attempt or was not successful in making its voice heard by the rank and file. It should be made manifest to the working classes that in so far as a medical man earns his living by practising medicine he is, economically speaking, in identically the same position as a skilled artisan who has had to serve a long apprenticeship to learn his trade; that he has the same right to form a trades-union, and, short of physical violence, may morally seek to coerce all members of the profession into joining the union; finally, that if a workman wishes to be well treated by his employer he must, when himself in the position of an employer, treat equally well those whom he employs. There are very few trades-unions in any part of the world which would not readily accept this argument. It is because benefit clubs have in their ranks a considerable number of middle-class men and small employers that these principles have not governed their relations with the medical profession. The latter will find its interests best understood, and best served, by appealing directly to the working-class element — particularly, as in this instance, the economic position and the personal interests of the working class and the medical profession are identical. Besides, as the secretary of the Medical Syndicate pointed out to me, the working men are absolutely robbed by the middle-class element. To use his own words, a rich man by joining a benefit society commits a crime. Charity concerts, bazaars, and other means are employed to raise funds to enable the benefit societies to relieve the poor. Money is spent and given to organise a medical service for that purpose; then a rich man comes and avails himself of this cheap medical service, thus appropriating to himself some of the money and services given expressly for the poor. This state of affairs, if properly understood, would never be approved by the working classes; but medical men, to carry this war to a successful end, must give themselves the trouble to thoroughly educate the masses on the question at issue.

Brussels, Aug. 24th.

THE FIFTH INTERNATIONAL CONGRESS AGAINST THE ABUSE OF ALCOHOL.

AS announced in THE LANCET of Aug. 10th, Bâle was the seat of this the Fifth International Congress for Combating the Abuse of Alcohol, and the 20th inst. the day of meeting. The attendance was considerable, not a few interested in the subject having taken a few days from their Swiss holiday to assist at the proceedings. The president of the Organising Committee, Dr. C. Ch. Burckhardt, bade the meeting welcome, and then the chair was taken by the Dutch Minister of State, M. Heemskerk, president of the permanent committee. His Excellency opened the proceedings by a brief *résumé* of the progress made in the movement since the last Congress at the Hague in 1893, after which three papers were read on the physiological and psychological effects of alcohol. Professor Gaula of Zürich, followed by Dr. Smith of Marbach and Dr. Fürer of Heidelberg, dwelt on the influence exerted by alcohol on the cerebral substance and on the deteriorating effects of the stimulant, even in moderation, on the memory and reasoning faculties. Intellectual work, the two latter contended, is always better during periods of abstinence than when strong drink is even sparingly indulged in. The discussion on these positions was slight, almost perfunctory, but became more animated when the reports of the directors of the lunatic asylums came to be read—reports of which Dr. Legrain of Paris and Professor Forel of Zürich had charge. Their conclusion was that lunacy increases in direct proportion to the abuse of alcohol. This, accepted in the main by M. Milliet, Director of the Federal Office for the Control of Alcohol, was supplemented by the same speaker in a modifying sense, his argument being against absolute disuse of alcohol, while he demonstrated the effect of other causes as responsible for many of the evils ascribed by Dr. Legrain and Professor Forel to alcohol alone. He was effectively supported by M. Bode of Hildesheim; but the preponderance of the meeting's sympathies was evidently in favour of total abstinence, Dr. Ridge being its eloquent and most uncompromising advocate. The first day's proceedings concluded with an elaborate paper by Dr. Lancelot, delegate of the French Minister of Public Instruction. His subject, ably treated, was the Characteristic Effects, Physiological and Psychical, of the Different Kinds of Alcoholic Beverages.

The second day (the 21st inst.) was devoted to the action of the various anti-alcoholic organisations throughout Europe, Monsignor Egger, Bishop of St. Gall, introducing the discussion with a special salutation from the Pope, who is well known as a promoter of the temperance cause. The leading participants in the proceedings were M. L. L. Rochat (representing Switzerland), MM. Bode and Tienken (who spoke for Germany), MM. Kraar and Bergmann (for Scandinavia), the venerable octogenarian Professor Valetan (for Holland), M. Wagener (for Denmark), and Miss Charlotte Gray, who related the work achieved in the different European countries by the Good Templars. From the *ensemble* of the speaking the conclusion was

Digitized by Google

inevitable that organised control of the consumption of alcohol is only on the threshold and that the results hitherto attained are, on the whole, satisfactory. The European countries where most progress of a real kind has been made are Norway and Sweden. As usual, the conflicting camps of "absolute abstention" on the one hand and "moderate use" on the other engrossed the greater part of the discussion—the result in point of argument, if not in point of numbers, being "drawn." Later in the day the Rev. Grant Mills and Dr. H. Christ gave interesting accounts of the appalling effects of alcohol among the savage tribes of Africa. This exposition suggested a modification of the Treaty of Brussels of 1890–91 in the direction of a far more stringent prohibition of the importation of alcohol into the Dark Continent. This modification, however, as a question of law, lay outside the power of the Congress, which had, therefore, to remain satisfied with putting on record its opinion. Two important papers followed from MM. Koblinski of Düsseldorf and Marthaler of Berne, penitentiary chaplains, who dwelt on the influence of alcohol in fostering crime. These, the second day's proceedings, were wound up by a banquet the simplicity of which proved no bar to much geniality, which found expression in effective speeches, all impressed with international fraternity.

The effect of alcoholic abuse in fostering crime was on the third and last day made prominent by M. Denis, who endeavoured by elaborate statistical returns to show the length to which European countries had gone in combating this source of criminality. France and Belgium, where no serious attempt has been made to restrain the spread of alcoholism, have, he said, the worst record in regard to crime. Switzerland and Holland, he contended, where the restrictive movement had already begun, had rendered crime "stationary," preluding a reduction in its prevalence as the movement became more energetic. Norway and Sweden, as already indicated, could boast of a distinct diminution in their criminal population, thanks to their control of alcoholism. From this the proceedings diverged into the subject of special asylums for drunkards. MM. Bleuler, Arnold-Bovet, Smith, and others contributed valuable expert evidence to its elucidation and strengthened the conclusion that these asylums should be multiplied, free from State control, and none of them on too large a scale—certainly not on the scale of that proposed in France to be established at the gates of Paris. Then the "full-dress debate" of the day was opened—on the State "monopoly in alcohol"—a principle ably advocated by M. Milliet as the only possible solution of the difficulty, at least in Switzerland, under present circumstances. On the other hand, its application to all countries indiscriminately was strenuously opposed by MM. L. L. Rochat and Moeller of Brussels, while M. Alglave supported it as an ideal to aim at. The afternoon sitting was employed in reorganising the permanent committee, so as to combine into one single committee the executive committee proper and the old permanent committee. Brussels was thereafter named as the seat of the next—the sixth—congress, to be held in 1897. After this, the subject of temperance cafés and restaurants was introduced, followed by the discussion of alcoholism in its relation to the working classes. The proceedings were at this stage enlivened by the intervention of a highly intelligent Socialist artisan, M. Bruno Gutsmann, who vigorously sustained the thesis that the cause of labour will never "find salvation" so long as the representative working man drinks, even moderately; contending at the same time that the state of society, as at present constituted, actually "condemned him almost fatally to alcoholism," a statement which was received with considerable reserve. M. Gutsmann was seconded by his fellow reporter, Mr. Martin Skinner, who replied to the objections raised against abstinence by a certain class of Socialists, and was in turn subjected to some vivacious but perfectly courteous criticism on the part of the "moderates." The concluding papers were occupied with the education of children in temperance principles—a well-considered subject on which the Congress was virtually unanimous.

The consensus of opinion on the Congress is a favourable one so far as its temper and ability are concerned—certainly it has been exempt from such scenes as characterised its predecessor of 1893 at the Hague. But—the besetting sin of all congresses—the agenda paper was far too crowded, the number and length of the papers sent in being out of all proportion to the time at the disposal of the Congress. Fewer subjects, more succinctly treated, and ampler notice given of their tenour, will in future be found a salutary innovation in the system hitherto adopted. As to the general arrangements for the convenience and comfort of the members, this latest one at Bâle contrasts favourably with all its predecessors. A special word of praise is due to the entertainments by which its labours were relieved—the *soirée* given by the abstaining students to the members in the Casino d'Été being particularly commendable for the refined hospitality by which it was characterised.

Bâle, Aug. 24th.

CHOLERA.

WE learn from Singapore that cholera was prevalent among the natives of this station during the summer, and that one European, an officer of the Northumberland Fusiliers, had succumbed to the disease.

But Japan is the country that has had a terrible experience of cholera of late, following the recent war and close communication with China and Corea. The epidemic in Japan attained large proportions and proved very fatal. Out of 25,000 cases 16,000 deaths were returned. We shall, no doubt, be furnished with a medical history of the epidemic by the Japanese medical authorities in the course of the year, and it will be interesting to ascertain the views entertained by an intelligent and very enterprising people as to the causes of the disease and the methods by which it is believed to have been introduced and spread in that country. So far as Europe is concerned, it is not likely that it will be affected by an extension of the epidemic from Japan.

The Vienna correspondent of the *Times* says that on the 23rd inst. a death took place at Tarnopol in Galicia and the provisional diagnosis of Asiatic cholera has now been confirmed by bacteriological examination.

THE CASE OF MR. R. B. ANDERSON.

THAT all British subjects are entitled to the benefits of an impartial administration of justice everywhere throughout this realm is a cardinal maxim of our legal system. The agents and exponents of the law are fallible, like other human beings, but hardships arising from this natural defect in most cases admit of reparation. The broad principles of justice are practically unalterable, and the security of individual members of the community is understood to be guaranteed by publicity and by the right of appeal. The conspicuous integrity of the administration of the law in England tends to foster this belief. Not within the present century have judges in this country been charged with systematic partiality, bias, and misuse of judicial powers. The same, however, cannot be said of all parts of the Queen's dominions. For some time past the columns of THE LANCET have contained frequent references to the remarkable hardships which have been illegally, but in the name of the law, inflicted on a member of our profession, Mr. R. B. Anderson, of the Island of Tobago, in the West Indies. This gentleman, who in 1873 became a Fellow of the Royal College of Surgeons of England, settled in Tobago, where he attained considerable success in practice and received the appointment of colonial surgeon, an office which after he had held it for five years was discontinued, Mr. Anderson receiving a pension by way of compensation. By the year 1889 he had been about sixteen years in practice in the island; he was, moreover, a justice of the peace, an elected member of the Legislative body, and a landowner. In that year, and after he had ceased to be the colonial surgeon, he was consulted by a coloured woman named Marshall, who suffered from limited necrosis of the lower jaw. After some months' preliminary attendance, necessitated by the unsatisfactory state of the patient's health, Mr. Anderson, with the assistance of a medical friend, cut down upon the sequestrum. It did not separate immediately, the patient's husband made himself objectionable, and after some weeks' further attendance Mr. Anderson suggested that they should seek other advice,

Digitized by Google

and retired from the case. About a fortnight after his attendance ceased, the sequestrum became loosened, and was easily removed by Dr. Tulloch, of Tobago, merely with his fingers. Mr. Anderson's professional charges not being paid, he took proceedings in the Petty Debt Court, and after some inexplicable delay found that the Chief Justice, Sir John Gorrie, who was then in the Island of Trinidad, had given special directions that this case was not to be tried until his (Sir John Gorrie's) arrival in Tobago. In the meantime Mrs. Marshall and her husband sued Mr. Anderson *in formâ pauperis* for £15 damages; there was no shadow of proof that the female plaintiff had sustained any injury, and the principal charge alleged against the defendant was neglect, inasmuch as he had improperly ceased to attend the plaintiff and retired from the case before recovery was complete. In the result the Chief Justice, in the beginning of 1890, gave judgment for the plaintiff for practically £17 10*s.*, with costs for breach of contract—for which the plaintiffs had not sued, neither had their plaint been amended to include it. Sir John Gorrie further stated, without any reservation, that a medical man, as such, and merely by becoming qualified, was bound to attend all cases of illness to which he was summoned, and that no medical man had a right, without the consent of the patient, to abandon any case which he had begun to treat, even where other medical aid was available and where the patient was running no risk from such abandonment, and that by so doing he laid himself open to an action at law, civil or criminal. He also stigmatised the making of contracts prior to attendance as an unprofessional and improper act on the part of the practitioner. It is almost needless to add that Mr. Anderson's claim for fees was disallowed by Sir John Gorrie. About a year afterwards—viz., on Jan. 20th, 1891—summonses in a non-medical case were taken out against Mr. Anderson. The plaintiff sued *in formâ pauperis*, no affidavit was made to show that the debts were unpaid, and the total amount of the judgment debts, including costs, was £42 2*s.* The case was tried in Tobago before Mr. Justice Cook, and Mr. Anderson was on Jan. 23rd ordered by this judge, upon adjournment of his examination, to give his security in £500 and also to find bail in £500 for his appearance at the adjourned hearing of the summons, and in default of giving such security he was committed to prison, where he remained until the adjourned hearing was resumed on Jan. 30th. On that day Mr. Justice Cook again adjourned the hearing after some examination and required Mr. Anderson to find security for his appearance, as before, in two sums of £500 each. Five well-known residents, three of whom were members of the Legislative Council, perceiving that a grave injustice was being perpetrated, went in a body to the judge to offer the security. Mr. Anderson was sent to England in 1891 by public subscriptions raised in Trinidad, to lay his wrongs before the home authorities and the public. On Sept. 14th of that year he instituted his remarkable action in the Court of Queen's Bench against the Trinidad judges (Anderson *v.* Gorrie and others). The facts disclosed were too flagrant to be overlooked. In 1892 a Royal Commission, consisting of Sir William Markby and Sir Frederick Pollock, was appointed to inquire into the administration of justice in Trinidad and Tobago, and their report resulted in the removal of Mr. Justice Cook from office. Sir John Gorrie was also interdicted pending the formal bringing of charges against him, but the interdiction was soon followed by his death. Mr. Anderson's action against the judges only came on in April, 1894, and occupied seven days, before the late Lord Chief Justice Coleridge and a special jury of Middlesex. In the course of the trial Lord Coleridge stigmatised the imposition of the bail already mentioned as "a piece of unmitigated, unlawful tyranny," and in the course of his summing-up said:—"The proceedings for contempt of court taken against the plaintiff for having petitioned the Queen were quite unjustifiable. Then judgments having been obtained against Mr. Anderson for £42, Mr. Justice Cook held him to bail for £500. He confessed he could not understand how an English judge could have so acted." The verdict was as follows:—"The jury find that the defendant Cook oppressively and with malice overstrained his judicial powers to the prejudice of the plaintiff and the wilful perversion of justice, and found a verdict for the plaintiff for £500." Lord Coleridge, however, entered judgment for the defendant on the ground that no action will lie against a judge for an act done in his judicial capacity, and this judgment has been confirmed by the Master of the Rolls, Lord Esher, and the Court of Appeal.

Mr. Anderson is, therefore, in an exceptional and almost unique manner the helpless victim of judicial persecution. He has been forced into heavy expenditure in the defence of his natural rights—an object so dear to every Englishman—and now he has the additional mortification of finding that the survivor of his persecutors is by a legal technicality placed above the ordinary operation of law, and thereby enabled to evade making reparation for his unlawful acts. Mr. Anderson's courage is admirable, but it is impossible to avoid pitying him. His thriving practice has been broken up, judgments unjustly given against him in Tobago are still in force and prevent him from returning to the island, whilst his means are consumed in the unequal struggle against an impassive officialism which admits the justice of his cause and the reality of his hardships but fails to provide redress.

FIFTH INTERNATIONAL CONGRESS OF OTOLOGY.

IN reference to this congress, which will be held at Florence from Sept. 23rd to 26th, Messrs. Thomas Cook and Son of Ludgate-circus, London, E.C., have made the following arrangements for issuing tickets to Florence by all routes. As delegates will be entitled to tickets at greatly reduced fares on the Italian railways by production of their certificate of membership at the railway station at the frontier, Messrs. Cook and Son also issue tickets to Modane, Vintimille, or Chiasso by all routes. The following are a few examples of the chief routes:—

Route.	Fares. Single journey from London to															
	Chiasso.				Modane.				Vintimille.				Florence.			
	1st Cl.		2nd Cl.		1st Cl.		2nd Cl.		1st Cl.		2nd Cl.		1st Cl.		2nd Cl.	
	£	s. d.	£	s. d.	£	s. d.	£	s. d.	£	s. d.	£	s. d.	£	s. d.	£	s. d.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Surrey County Sanitary District.—Dr. Edward Seaton's report for this district during 1894 is arranged in subject sections; in each section, in addition to a general review by the county medical officer, is given a synopsis of those parts of the district reports relating to the subject. During the year 1894 Dr. Seaton attended numerous conferences and Government inquiries, made a large number of inspections, and drew up several reports. In reference to the county medical officer of health's attendance at Government inquiries an instruction has been drawn up by the council and inserted in the standing orders, that as far as possible he shall attend all such inquiries as relate to the public health of the county for the purpose, in the first instance, of affording to the inspector holding the inquiry any information in his power. He is, however, not to appear as a witness on either side save in cases where his advice has been sought by the sanitary authorities and given to them after consultation with, and with the consent of, the sanitary committee of the county council. Dr. Seaton records considerable improvement in the reports of the district medical officers of health, though there is, he states, still a wide difference between those drawn up by those who devote their whole time to the duties of their office and those who do otherwise. In certain districts Dr. Seaton remarks that substantial improvement in the sanitary condition can only be brought about by the amalgamation of districts and the appointment of medical officers of health who shall devote all their time to their work. The county general death-rate was for 1894 but 11·9—i.e., 2 per 1000 less than the average of the previous quinquennium. Notification is now common throughout the county, and Dr. Seaton, in referring to the influence which county opinion has had upon the general adoption of the Notification Act, alludes to the case of Buckinghamshire, where, as he remarks, the attempt by the county council to cultivate a county opinion has signally failed. Certainly this is so, if we may take the vitality of the Buckinghamshire sanitary committee as evidence. In the matter of zymotic disease diphtheria presents a depressing aspect, giving rise as it did during 1894 to a death-rate of 25 per 100,000 in the urban districts and 38 per 100,000 in the rural districts. Comparing these rates with those for scarlet fever, we learn that this disease causes a death-rate of but 2 per 100,000 in the urban, and 5 per 100,000 in the rural districts. Enteric fever again caused a death-rate of 9 per 100,000 in the urban and 8 per 100,000 in the rural districts. The subject of isolation provision has received much attention during the past year, but Dr. Seaton regrets that he is unable to chronicle the carrying out of any scheme. The water-supply of the county is dealt with very fully and lucidly by Dr. Seaton, and he states that in many of the rural parts of Surrey water from surface wells is still general, in spite of the fact that in certain parts of the district a far safer supply is easily procurable. With reference to the river-water supplies, the need for extending the mains of some of the metropolitan companies and of the West Surrey and South-west suburban companies is insisted upon. There is no evidence, Dr. Seaton remarks, that the floods of 1894 have produced any ill effects as regards the health of the county so far as the river water-supplies are concerned. A very concise synopsis of "Subjects of Importance" referred to by the medical officers of health in the county is given in the form of a sheet in Dr. Seaton's very interesting report, which shows at a glance those matters which are receiving attention and those which are not. The report also gives an abstract of the quarterly reports of the county analyst and of the chief inspector under the Contagious Diseases (Animals) Act.

Essex County Sanitary District.—Calculated upon the usual basis, the population of the administrative county of Essex was in the middle of last year 635,590, that of the urban districts being 363,620, and that of the rural 271,970. The birth-rate for 1894 was in the urban districts 30·2, and in the rural 26·2 per 1000. Commenting upon the decreases which these rates evince, Dr. Thresh observes that there is a disposition to view a declining birth-rate with satisfaction without inquiry as to its cause, the fact that the cause or causes may be anything but satisfactory being ignored. The general death-rate in the urban districts of the county was 13·0 per 1000, and in the rural districts 13·3. Dr. Thresh remarks that these remarkably low death-rates may be due in some degree to favourable meteorological conditions, and also to the devastating influence of influenza which occurred in previous years. We cannot hope, he points out, to reduce our general death-rate to 13·1 per 1000 before many years have been spent in sanitary reform and in the education of the people in all that makes for longevity. The infantile mortality for the whole county was during 1894 but 109 per 1000 births. In the matter of zymotic diseases the most noticeable feature in the county statistics is the fact that both in the urban and rural districts diphtheria is accountable for more deaths than small-pox, scarlet fever, typhoid fever, and measles combined, the diphtheria death-rate being nearly twice that for England and Wales. The mortality from this disease in the rural districts was smaller in proportion to the population than in the urban districts; but the

Digitized by Google

fatality rate in the former was rather in excess of that in the latter, a difference which may be due, Dr. Thresh thinks, to the disease frequently assuming a more severe type in country districts than in towns or to trivial cases escaping observation. Possibly greater facility for medical and surgical assistance may, we would suggest, have had some effect. Dr. Thresh undertakes the bacteriological examination of any case of suspected diphtheria, and he supplies culture boxes to medical practitioners in the county, containing minute instructions for the inoculation of the tubes, &c. One instance—an instructive one—is mentioned by Dr. Thresh, in which an inoculation made on one day showed no diphtheria bacilli, while on the following day another inoculation from the same case yielded positive results. There is still much work to be done in Essex in the matter of isolation and provision for disinfection. During 1894 only 10·3 per cent. of notified cases of infectious disease in the urban districts were isolated in hospital; in the rural districts only 5·7 per cent. Only four districts in the county possess a modern form of disinfecting apparatus. In the latter connexion, however, we hear that Dr. Thresh has himself invented a disinfecting apparatus which possesses both efficient and economical qualifications. The reports of the district medical officers show, Dr. Thresh states, a steady and marked improvement; he regrets, however, as also do we, that in the rural districts only 16 out of 20 of the reports are printed, and in the urban only 11 out of 20. To take a medical officer of health's report as read, and evince no further interest in it, is certainly not the way to stimulate this officer to increased activity, but we fear that in some instances it is this very activity which it is the desire of the sanitary authority to check.

Oldham Urban Sanitary District.—In Mr. Charles H. Tattersall's first annual report on the sanitary condition of Oldham there is contained an instructive table, which we here reproduce, showing the incidence of small-pox around the Westhulme Hospital during the periods of its operations both in 1893 and 1894. In the former year, as our readers will probably remember from the valuable reports of Dr. James Niven, cases of acute small-pox were treated in the hospital in question; but in consequence of the increased incidence of the disease upon the surrounding districts arrangements were made for isolating future cases in a locality well remote from aggregations of population. The acute cases, however, during the last outbreak were brought back on becoming convalescent to the Westhulme Hospital. In the following table are given the number of untraced cases of small-pox and the percentage of houses affected upon the areas comprised within the several zones of the hospital, and it will be apparent that while in 1893 the percentage of houses invaded decreased with the distance from the hospital, no such incidence obtained in 1894:—

—	Total number of houses in 1893.	1893. Number of cases untraced in 1893.	1893. Percentage of houses affected.	1894. Number of untraced cases in 1894.	1894. Percentage of houses affected.
Within ½-mile radius of Westhulme Hospital ...	170	10	5·8	0	0·00
Zone ½ to ¾ mile	1,660	62	3·7	3	0·18
Zone ¾ to ¾ mile	2,450	40	1·6	4	0·16
Zone ¾ to 1 mile	5,000	46	0·9	10	0·20
Outside 1 mile radius ...	20,250	49	0·2	19	0·09

The total number of cases in 1894 was perhaps too small to place much reliance upon, but it will be observed that the different effects upon the surrounding population of aggregating on the one hand acute cases of the disease, and on the other the convalescent cases, are parallel with those demonstrated to have occurred over and over again by Mr. W. H. Power, F.R.S., in connexion with the operations of the Fulham Small-pox Hospital. The method adopted by Mr. Tattersall of calculating what he terms *untraced* cases only seem to us not unlikely to involve a fallacy, inasmuch as it assumes that, given a person who has two possible opportunities of being infected, one by personal contagion and the other by means of air-borne infection, the former is necessarily the more probable source of infection. The question is whether we are in a position to take up this standpoint, and whether we are justified in excluding from our calculations all such cases as might possibly have become personally affected. Anyhow, this method cannot be accused of any undue leniency towards aërial convection.

Halifax Urban Sanitary District.—Mr. D. Ainley, in presenting the current annual report, refers to the fact that Halifax has for many years ranked high amongst other towns in the matter of uncertified deaths, and with a view of throwing some light upon this subject he visited during the last five months of 1894 every case returned as uncertified. In some instances the non-certification appears to have been due to the attendance of an unqualified locum-tenens; in others, again, to the attendance of a midwife; and in yet others sudden death from chronic heart disease seems to have been the explanation. In some cases the medical practitioner arrived after death had taken place. Mr. Ainley considers that the small proportion of inquests held in Halifax in cases of uncertified deaths is the chief reason of the excess referred to. Mr. William Ackroyd, the public analyst for Halifax, condemns the practice of greening peas with sulphate of copper, and he insists that too much publicity cannot be given to the fact that French canned peas are thus coloured. The practice is illegal in France, but this fact does not appear to prevent its continuance. Both the samples analysed by Mr. Ackroyd in Halifax in 1894 contained sulphate of copper, one to the extent of fifteen grains per pound.

Hackney Urban Sanitary District.—In his annual report for 1894 Dr. King Warry furnishes a very interesting account of an outburst of diphtheria and infective sore-throat which occurred in a workshop in his district giving employment to some 160 persons. The attacks, 26 in number, were, with 3 exceptions, distributed among 43 adult females occupying a certain workroom. The disease was in the first instance imported from without, and having been introduced it appears to have spread through the agency of infected speaking-tubes and lavatory towels. The 3 earliest attacked were those who habitually made use of the speaking-tubes in question, and the tubes becoming infected were instrumental, in large part at least, in conveying the disease to employés subsequently using them. Of the remaining 3 cases, 1—an occupant of the room below the infected workshop—devoted part of her time to answering the speaking-tubes from the infected workshop; the other 2 were found upon inquiry to have used, contrary to regulations, the lavatory and towels belonging to the inmates of the infected workroom. It may be remarked that the workroom was not, in the sense of the Factory and Workshops Act, overcrowded, and that it was both well lighted and ventilated.

Durham County Sanitary District.—Dr. Eustace Hill, as in former years, prefaces the annual summary of the district medical officers' reports with a general report on the sanitary condition of the county generally. The total population of the administrative county, estimated to the middle of 1894, was 754,494, and in connexion with this estimate Dr. Hill states that some of the district medical officers in their annual reports for 1894 give simply the census population of 1891, while in other districts no recognised method of calculation has been adopted. The general death-rate for the administrative county was 17·2 per 1000—i.e., 2·8 per 1000 less than in the previous year. In the urban districts the rate was 16·9 and in the rural 17·7. The percentage of uncertified deaths to total deaths was 4·08, a rate which exceeded that for England and Wales by 1·58. This large proportion of uncertified deaths is, Dr. Hill remarks, entirely the result of medical practice by unqualified persons. The one serious blot upon the vital statistics of Durham county is the excessive typhoid fever rate; there were during 1894 259 deaths, the death-rate for the county—0·34 per 1000 of the population—being nearly double that for England and Wales. Several local outbreaks were apparently due to the consumption of specifically polluted water, and in the districts where notification is in force the cost of its operation amounted to £1 7*s.* 9*d.* per 1000 of the population. Only 8·8 per cent. of the notified cases were isolated in hospital during 1894, as compared with 11·7 per cent. for 1893. Under the Housing of the Working Classes Act good work has, Dr. Hill reports, been carried out, and he considers that Part III. of the Act might with advantage be brought into operation in some of the rural districts in the county. There is certainly room for at least some experiments under this part of the Act, whether in Durham or elsewhere. In the matter of scavenging we are

Digitized by Google

glad to learn that the Local Government Board has, after an inquiry, compelled the Durham rural sanitary authority to themselves undertake this work in most of the populous places in their district. As regards rivers pollution, the action of the County Council in taking proceedings against the urban sanitary authorities of Durham and Barnard Castle will be welcomed by all sanitary reformers.

Chester County Sanitary District.—The administrative county of Chester, for which Mr. Francis Vacher is medical officer of health, had in the middle of 1894 an estimated population of 555,211; the number of persons per acre was 9·98 in the municipal boroughs, 3·21 in the other urban districts, and 0·34 in the rural districts. The general death-rate in the municipal boroughs was 16·5, in the other urban districts 16·0, and in the rural districts 14·8 per 1000. The infantile mortality of the administrative county varied from 236 per 1000 births in Mottram to 26 in Higher Bebington. In referring to the subject of typhoid fever, Mr. Vacher draws attention to an interesting outbreak of the disease which occurred in the Northwich rural sanitary district, and which is reported upon by Mr. J. M. Fox, the district medical officer of health. The disease, in the first instance imported, appears to have spread through the agency of a mismanaged scavenging department; almost every person in any way engaged with the management of the scavenging became affected with the disease. There appears to have been a further complication in this instance in that the chief scavenger was a milk-seller. Mr. Vacher reports that outbreaks of rabies occurred in various parts of the county during the latter part of 1894, and in the borough of Hyde several children were bitten by rabid animals. The town council of this borough very generously sent those bitten to Paris under the supervision of the medical officer of health and the matron of the isolation hospital to undergo treatment at the Pasteur Institute. Mr. Sidebotham, medical officer of health of Hyde, furnishes in his current annual report a short account of his visit to Paris, which, as Mr. Vacher suggests, will be read with much interest by medical officers of health who have equally generous sanitary authorities to deal with. It may be remarked that the diagnosis of rabies in the dogs that bit the patients sent by the Hyde corporation was experimentally confirmed in Paris. Notification is not yet general in Cheshire, there being still four urban and one rural districts where the Act is not in force. The 555,000 persons comprising the population of Cheshire are still very badly off in the matter of isolation accommodation, but doubtless the valuable report which Mr. Vacher has made to the County Council upon the subject will have a stimulating effect. Mr. Vacher goes very thoroughly into all matters connected with the health of the county, and in connexion with each subject he sets forth the powers and responsibilities of the sanitary authority, and discusses the manner in which throughout the county these obligations are carried out. Under the heading of "Unsound Meat" Mr. Vacher observes that "either there is practically no trade in unsound meat &c. in this large county or the trade is not interfered with—the subject is only alluded to in four reports."

Kensington Urban Sanitary District. — Dr. Orme Dudfield's report for the year 1894 is, as usual, full of instructive matter, and will well repay reading by all interested in the sanitary progress of the metropolis. The report comprises some 260 pages of printed matter devoted to subjects connected not only with the parish of Kensington, but also with the metropolis as a whole. The estimated population of Kensington in the middle of 1894 was 167,300, and the ratable value in April of the same year £2,064,073. The population of the parish is to that of London as 1 to 26, and the ratable value as 1 to 16·4. The birth-rate of Kensington was but 21·9 per 1000, that for the town subdistrict being 25·7, and that for the Brompton district 12·6. The illegitimate birth-rate formed 5·8 per cent. of the total births, as compared with rates of 5·4, 4·9, and 4·9 in the preceding three years respectively. The general death-rate in the town subdistrict was 17·6 per 1000, that in Brompton being 11·0; the rate in the male sex was 19·8 and in the female sex 12·9. The total death-rate for the district, 15·7 per 1000, was 1·3 below the decennial average. Under the heading of small-pox Dr. Dudfield refers to a group of cases the first of which was not notified, owing, apparently, to its not being recognised until twenty days after its commencement. Cases such as these show well the limits which are experienced in practice to the utility of notification, and the difficulties of dealing with small-pox without the aid of vaccination and revaccination. As in former years, the report before us contains a most useful summary of the Metropolitan Asylums Board's annual reports; and we are, too, glad to see that the really admirable report of the women inspectors of Kensington, which we noticed in our columns at the time of its issue, is embodied in Dr. Dudfield's annual report of the district. Complaints occurred in Kensington during 1894 owing to a nuisance at a certain gasworks, caused apparently during the removal of spent lime from the gas purifiers. At Dr. Dudfield's suggestion some improvements were effected, but it appears that the nuisance cannot be entirely eliminated. In the matter of a temporary shelter Kensington is still classed with the metropolitan sanitary authorities who have failed to carry out the obligatory provisions of Section 61 of the Public Health (London) Act, 1891, although the subject has, to our knowledge, been frequently brought to the notice of the vestry. The medical officer of health states that during 1894 some sixty-four cases of infectious disease occurred in families occupying single rooms, and in each instance the room was closed for twenty-four hours. We are not told what became of the families during the period of their enforced absence from home.

Battersea Urban Sanitary District.—Dr. W. H. Kempster's report for 1894 should prove a highly interesting one to the sanitary authority for which it is prepared, as it contains a synopsis both of the report of the Royal Commission on the Metropolitan Water-supply and of the criticisms in it as prepared by the officers of the London County Council. In the conclusion of his summary Dr. Kempster observes: "It has always been a cherished article of faith in this country that the water of the river Thames is of unsurpassable quality for all domestic purposes. Nothing can be found in the report which in any way disturbs this conviction, and it may be assumed, as has always been urged in these reports, that the water supplied to London, if properly treated by the avoidance of pollution, ample storage ..... and efficient filtration, is all that can be desired." The existence of the "cherished article of faith" to which Dr. Kempster refers would not, perhaps, be admitted on all hands. There is also a capital summary in the report before us of the provisions of Mr. Asquith's Factory and Workshops Act. Very considerable improvement has been effected in Battersea during 1894 in the matter of public-house urinals as a result of a detailed inspection by a subcommittee of the sanitary authority; this action might be followed with profit in other metropolitan districts. Proceedings were taken in Battersea last year against the vendor of certain cheeses unfit for consumption, but the magistrate inflicted the costs only, and observed that a certain degree of decomposition was allowable in cheese. In, however, the case in question the cheeses were stated to have been in such a condition that the odour from them could be detected 200 yards away, and they were being sold for 2*d.* and 2½*d.* per pound. It seems that these cheeses had been stored in cellars which had been frequently inundated with Thames water, and this fact should certainly have precluded their sale.

Cardiff Urban Sanitary District.—From the view-point of public health the year 1894 will stand out prominently in the history of Cardiff as one in which marked advance was made. In the first place, it was in that year that the Cardiff Corporation Act became law, an Act which, besides containing several clauses bearing indirectly upon the public health, confers important powers upon the corporation in respect to dwelling-houses without proper water-supply, erection of dwellings on flat lands below high-water level, and the erection and maintenance of a crematorium for human remains. A fresh water-supply was introduced and a most complete fever hospital proceeded with. Dr. Edward Walford also, in his annual report, refers to the prospect of a public health laboratory being established at University College, Cardiff, in conjunction with the sanitary authority of that town, in which case facilities for bacteriological examination &c. would be afforded to the medical officer of health. Dr. Walford has been at much trouble to set forth clearly the birth- and death-rates for Cardiff, and he supplies some excellent tables in his report. From 1845 to 1884 the mean death-rates per 1000 for each ten years were as follows: 32·7, 26·7, 23·6, 20·0, and 20·7; the zymotic death-rates for the same periods were 9·8, 5·4, 3·9, 3·3, and 2·7.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN thirty-three of the largest English towns 6224 births and 4045 deaths were registered during the week ending

Digitized by Google

Aug. 24th. The annual rate of mortality in these towns, which had been 20·8 and 19·1 per 1000 in the two preceding weeks, rose again to 19·9 last week. In London the rate was 17·0 per 1000, while it averaged 22·0 in the thirty-two large provincial towns. The lowest rates in these towns were 11·8 in Croydon, 12·4 in Swansea, 12·9 in Plymouth, 15·5 in Bristol, and 15·9 in Leicester; the highest rates were 28·2 in Liverpool, 29·0 in Salford, 30·4 in Manchester, 33·2 in Hull, and 35·6 in Blackburn. The 4045 deaths included 977 which were referred to the principal zymotic diseases, against 1076 and 929 in the two preceding weeks; of these, 657 resulted from diarrhœa, 115 from measles, 64 from whooping-cough, 47 from diphtheria, 46 from scarlet fever, 40 from "fever" (principally enteric), and 8 from small-pox. In the large towns these diseases caused the lowest death-rates in Bristol, Croydon, Swansea, Halifax, and Plymouth; and the highest rates in Bolton, Wolverhampton, Salford, Hull, and Blackburn. The greatest mortality from measles occurred in West Ham, Salford, and Blackburn; from whooping-cough in Liverpool, Gateshead, Blackburn, and Birkenhead; and from diarrhœa in Sheffield, Derby, Wolverhampton, Preston, Salford, Bolton, and Hull. The mortality from scarlet fever and from "fever" showed no marked excess in any of the large towns. The 46 deaths from diphtheria included 24 in London and 3 in Liverpool. Six fatal cases of small-pox were registered in London and 2 in Oldham, but not one in any other of the thirty-three towns. There were 357 cases of small-pox under treatment in the Metropolitan Asylum Hospitals and in the Highgate Small-pox Hospital on Saturday last, the 24th inst., against 237, 273, and 336 at the end of the three preceding weeks; 65 new cases were admitted during the week, against 60, 54, and 79 in the three preceding weeks. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 2507, against 2423, 2511, and 2529 on the three preceding Saturdays; 307 new cases were admitted during the week, against 247, 276, and 357 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 159 and 137 in the two preceding weeks, rose again to 170 last week, and were 1 below the corrected average. The causes of 31, or 0·8 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Bristol, Nottingham, Bradford, Hull, Newcastle, and in seventeen other smaller towns; the largest proportions of uncertified deaths were registered in Blackburn and in Birkenhead.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 17·6 and 16·6 per 1000 in the two preceding weeks, was again 16·6 during the week ending Aug. 24th, and was 3·3 per 1000 below the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 12·1 in Leith and 15·0 in Glasgow to 20·6 in Perth and 21·4 in Aberdeen. The 479 deaths in these towns included 42 which were referred to diarrhœa, 24 to whooping-cough, 8 to scarlet fever, 6 to to "fever," 2 to measles, 1 to diphtheria, and not one to small-pox. In all, 83 deaths resulted from these principal zymotic diseases, against 102 and 99 in the two preceding weeks. These 83 deaths were equal to an annual rate of 2·9 per 1000, which was 1·9 below the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of diarrhœa, which had been 55, 68, and 60 in the three preceding weeks, further declined to 42 last week, of which 17 occurred in Glasgow, 10 in Edinburgh, and 9 in Dundee. The deaths referred to whooping-cough, which had been 12, 17, and 15 in the three preceding weeks, rose again to 24 last week, and included 6 in Glasgow, 5 in Dundee, and 4 in Aberdeen. The deaths from scarlet fever, which had increased from 3 to 7 in the three preceding weeks, further rose to 8 last week, of which 6 occurred in Glasgow. The fatal cases of "fever," which had been 5, 4, and 6 in the three preceding weeks, were again 6 last week, and of these 4 occurred in Glasgow. The deaths from measles, which had decreased from 11 to 7 in the four preceding weeks, further fell to 2 last week, and included 1 in Glasgow and 1 in Greenock. Only 1 death from diphtheria was recorded, being 3 less than in the preceding week, and that occurred in Dundee. The deaths referred to diseases of the respiratory organs in these towns, which had been 67 and 57 in the two preceding weeks, further declined to 55 last week, but exceeded by 4 the number in the corresponding week of last year. The causes of 31, or nearly 7 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 22·2 and 24·0 per 1000 in the two preceding weeks, fell again to 20·9 during the week ending Aug. 24th. During the past eight weeks of the current quarter the death-rate in the city has averaged 23·3 per 1000, the rate during the same period being 20·1 in London and 16·5 in Edinburgh. The 140 deaths registered in Dublin during the week under notice showed a decline of 21 from the number in the preceding week, and included 11 which were referred to the principal zymotic diseases, against 27 and 21 in the two preceding weeks; of these, 9 resulted from diarrhœa, 1 from scarlet fever, 1 from whooping-cough, and not one from small-pox, measles, diphtheria, or "fever." These 11 deaths were equal to an annual rate of 1·6 per 1000, the zymotic death-rate during the same period being 3·0 in London and 0·8 in Edinburgh. The fatal cases of diarrhœa, which had been 17, 23, and 16 in the three preceding weeks, further fell to 9 last week. The mortality from whooping-cough corresponded with that recorded in the preceding week, while that from scarlet fever showed a decline. The 140 deaths in Dublin last week included 26 of infants under one year of age, and 32 of persons aged upwards of sixty years; the deaths both of infants and of elderly persons showing a decrease. Seven inquests were held and 8 deaths from violence were registered; and 45, or nearly a third, of the deaths occurred in public institutions. The causes of 10, or more than 7 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

ARMY MEDICAL STAFF.

SURGEON-LIEUTENANT-COLONEL RANDOLPHE HARMAN, M.B., to be Brigade-Surgeon-Lieutenant-Colonel.

INDIA AND THE INDIAN MEDICAL SERVICES.

Surgeon-Captain H. B. Luard, at present officiating Agency Surgeon at Gilgit, is appointed to the permanent Medical Charge of the 45th Sikhs, and Surgeon-Captain G. H. Frost to the permanent Medical Charge of the 22nd Punjaub Infantry. Surgeon-Major R. J. Baker, M.D. (Bombay), Officiating Medical Officer of the 2nd Regiment, Central India Horse, and of the Poona Political Agency, is appointed to officiate as Medical Officer of the 1st Regiment, Central India Horse, and of the Western Malwa Political Agency, and during the absence on leave of Surgeon-Captain T. W. Shaw, M.B., or until further orders. Surgeon-Major A. E. J. Croly, F.R.C.S.I., is appointed to act as Medical Officer on the staff of his Excellency the Governor during the absence of Surgeon-Major H. Martin, M.B., or pending further orders.

NAVAL MEDICAL SERVICE.

The undermentioned surgeons have been promoted to the rank of Staff-Surgeon in Her Majesty's Fleet:—Edward John Morley, Hugh Winckworth Macnamara, Joseph Henry Whelan, M.D., Percy William Bassett-Smith, John Patrick Joseph Coolican, Edgar Ralph Dimsey, Joseph Reville McDonnell, M.D., Hamilton Meikle, and Herbert Canton.

The following appointments are announced:—Staff-Surgeon J. H. Whelan to the *Volage*. Surgeons: James L. Smith, M.B., to the *Blonde*; Frederick Fedarb, M.B., to Haslar Hospital; E. P. Mourilyan to the *Cormorant*; W. J. Maillard to the *Excellent*; F. Bradshaw to the *Plassy*; H. Elliott to the *Sphinx*; T. Austen to the *Wildfire*; G. Ley to Bermuda Hospital; H. S. Burniston to the *Active*; J. H. Thomas to the *Pembroke*; G. Welch to the *Tyne*; and E. St. M. Nepean to the *Victory* (additional).

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Lieutenant Percival M. Yearsley, having vacated his Volunteer Medical appointment, ceases to be an Officer of the Army Medical Reserve of Officers.

VOLUNTEER CORPS.

Rifle: 1st Volunteer Battalion the Suffolk Regiment;

Digitized by Google

Surgeon-Lieutenant P. J. L. Morris resigns his commission. 2nd Volunteer Battalion the Suffolk Regiment: Samuel John James Kirby, M.D., to be Surgeon-Lieutenant. 1st (Cumberland) Volunteer Battalion the Border Regiment: Surgeon-Lieutenant S. Braithwaite resigns his commission. 1st Volunteer Battalion the Gordon Highlanders: Surgeon-Lieutenant G. M. Edmond, M.D., to be Surgeon-Captain.

THE ARMY REORGANISATION.

The Ministerial statement in the House of Lords in reference to the forthcoming reorganisation of the War Office is sufficiently clear and explicit as far as it goes. The new policy is not only based upon, but it is almost identical with, the recommendations of the Hartington Commission, except in one important particular—viz., that there will not be a Chief of the Staff appointed as recommended by that Commission. Lord Wolseley will for the next five years be the military head of the Queen's Army and exercise those functions which have hitherto been discharged by the Duke of Cambridge. There are, of course, a number of other important points embodied in the new scheme of reorganisation, but the foregoing really includes the main considerations of interest to the army and the nation.

DEATHS IN THE SERVICES.

Brigade-Surgeon-Lieutenant-Colonel J. F. Sargent, I.M.S., Madras Establishment, died at Hingoli on July 20th from abscess on the liver, aged fifty-one. He was appointed surgeon in 1873 and surgeon-major in 1878, and attained the rank of brigade-surgeon-lieutenant-colonel in 1890.

Brigade-Surgeon-Lieutenant-Colonel J. Riddick, A.M.S., died in India on July 27th. He joined the Army in 1857, became surgeon in 1873, surgeon-major in 1879, and brigade-surgeon-lieutenant-colonel in 1894; Afghan War, 1880, (medal).

THE WAZIRISTAN HONOURS.

Surgeon-Colonel Lionel Dixon Spencer, I.M.S., is to be Ordinary Member of the Military Division of the Third Class, or Companion, of the Most Honourable Order of the Bath, and Brigade-Surgeon-Lieutenant-Colonel George McBride Davis, I.M.S., is to be a Companion of the Distinguished Service Order.

The War Office have instructed Messrs. Paterson and Cooper to proceed with the erection at Netley Hospital of the Hermite sanitation plant, the cost of which has been provided for in this year's Parliamentary estimates.

Correspondence.

"Audi alteram partem."

COUNTRY PRACTITIONERS AND LOCUM-TENENTS.

To the Editors of THE LANCET.

SIRS,—Kindly allow me space for a few remarks about the troubles, losses, &c. country practitioners experience from individuals they engage to take charge of their practices whilst taking the much-needed holidays. My experiences have been very painful, but, I believe, not worse than those of other general practitioners. Out of seven (all except Nos. 1 and 7 were supplied by agents) No. 1 alone gave satisfaction. No. 3 lamed my horse by jumping it over fences or by other work it was not fitted for. No. 5 took fright at a case of small-pox and bolted after helping himself to money he was not entitled to. No. 6 was so drunken that I had to give up my holiday at an hour's notice to get rid of him just before he had delirium tremens. In fact, all except No. 1 acted as if on a holiday or spree, doing as little as possible and never booking that little legibly or fully, neglecting patients, and during such few hours they thought fit to stay in my house making themselves as untidy, slovenly, and disagreeable as possible. These gentlemen demand three guineas a week, board, lodging, and all expenses. Having got all immediately after the employer's return, there are no means of calling them to account, as their delinquencies are only discovered later on, after their being paid and dismissed. I suggest that two recent references should be required from each applicant, and that even if he is recommended by an agency. If honest replies are sent, then the necessary holiday can be taken without the losses and annoyances I have written about. I quote the following from a letter from a country practitioner whom, although I have never met him, I am glad to know I warned against employing as locum-tenent one of the most ungentlemanly persons that I ever met with. He writes as follows: "I deeply sympathise with your having been served the same way as myself by such worthless, indifferent, and incompetent men going about the country. ..... I am determined before I engage another man to find out his antecedents. ..... If employers were more honest and truthful much heart-burning would be saved." I trust general practitioners will take the advice given by my correspondent, and not only decline to recommend but expose anyone who does not carry out his duties and behave himself as a gentleman ought to do whilst in their employ.

I am, Sirs, yours faithfully,

HENRY PILKINGTON, M.R.C.S. &c.

Ormskirk, Lancs, Aug. 26th, 1895.

THE PAYMENT OF MEDICAL WITNESSES.

To the Editors of THE LANCET.

SIRS,—My partner and I had to attend the last Assizes held at Lincoln as medical witnesses in a manslaughter case. On each of three days we had to leave home at 9.20 A.M. On two of the days the earliest time we could possibly get back was 5.20 P.M., and on the third day 1 P.M. We were paid one guinea per diem each, and an allowance of 12*s.* 10*d.* each for expenses—a total of £3 15*s.* 10*d.* for an enforced absence from our practice of nineteen hours and forty minutes. I am writing you this simple statement hoping that you, or some of the numerous readers of THE LANCET, will suggest some means whereby united action can be taken, in order that the present state of things may be altered, so that medical witnesses in similar cases shall be paid reasonable fees for their loss of time and trouble.

I am, Sirs, yours faithfully,

Gainsborough, Aug. 22nd, 1895. JOHN E. S. PASSMORE.

*** Our correspondent will note that the subject-matter of his letter is dealt with in a leading article in our present issue.—ED. L.

"AN IMPOSTOR."

To the Editors of THE LANCET.

SIRS,—The letter you publish in THE LANCET of Aug. 24th from Dr. F. W. Saunders has interested me, for I, too, was favoured the other day from the Goswell-road. In this case the writer signs himself Arthur E. Ronald, which is the name of an old friend of mine who was at Cambridge and St. Thomas's Hospital with me. The letter asks for an immediate loan and promises subsequent explanations. Certain circumstances and signs, however, made me doubt the genuineness of the communication and so save myself from the imposition. A friend of mine writes to me from Cambridge and tells me that a short time ago he actually fell a victim to some (probably the same) rascal, who wrote to him from an address in the Gray's-inn-road, signing himself George Anson, and asking for an immediate loan. In these two instances the four persons written to and from were intimate friends both at Cambridge and at Thomas's Hospital. Drs. Ronald and Anson are at present in practice abroad, the former in Melbourne and the latter in New Zealand. The letters show that their whereabouts were well known to the writer.

I am, Sirs, yours faithfully,

EDGAR TREVITHICK, M.D. Cantab.

Cheltenham, Aug. 23rd, 1895.

"THE TREATMENT OF ACUTE RHEUMATIC ENDOCARDITIS."

To the Editors of THE LANCET.

SIRS,—In THE LANCET of Aug. 17th there is a valuable contribution to this important question by Dr. Caton of Liverpool. I should not have been prompted by the general tenour of his paper to trouble you with any words from me on the subject, but I am tempted to accede to his request when he so pointedly says, "I am anxious to know what the

Digitized by Google

experience of others has been in regard to the very grave disease in question, and to hear of alternative or superior plans of treatment. The one thing I am specially anxious about is that members of the profession who have the opportunity of observing cases of acute endocarditis should give this method a fair trial during the early stage of the malady." In the first place, as regards the occurrence of acute endocarditis in the course of, or as a sequel to, a more or less acute rheumatic attack, I doubt if there is any very general recognition of the condition apart from the existence of murmur, and even when murmur is present it is of course a question whether it is or is not due to inflammatory changes in the endocardium. This question, along with some others, I dealt with ten or eleven years ago in a little volume entitled "Investigations into some Morbid Cardiac Conditions," and I do not enter into it now. Most of us will be prepared to accept Dr. Caton's opinion of his own cases as the expression of a reasonable diagnosis. At page 144 of the book referred to I mention that I had treated three cases of what I believed to be active endocarditis by blistering the præcordia and giving iodide of potassium internally, and that the result in these cases was different from others I had not so treated in that they recovered. Since that book was published I have been confirmed in my then expressed opinion that active endocarditis was capable of being diagnosed even when superadded to a previously damaged endocardium; and eleven years of additional experience have only tended to establish in my mind the value of the treatment which Dr. Caton has advocated.—I am, Sirs, yours truly,

WM. RUSSELL,
Assistant Physician, Royal Infirmary.

Edinburgh, Aug. 26th, 1895.

DIPHTHERIA AND ITS CAUSATION.

To the Editors of THE LANCET.

SIRS,—The two chief views put forward to account for the various outbreaks of diphtheria that occur from time to time are (1) defective sanitation, and (2) the aggregation of children in schools. This latter has been specially put forward by Mr. Shirley Murphy, medical officer of health to the London County Council; but with regard to school attendance Mr. Biddle has shown that, though the number of cases increases (as Mr. Shirley Murphy asserts) immediately after the holidays, they decrease again as the term drags on its course. At first sight it appears as if these two ideas are utterly irreconcilable, but I cannot help thinking both may possibly be right. It must be considered that there is no flushing of the school drains during the holidays, and that they only get properly scoured and disinfected after the children meet. I dare say others besides myself have noticed the prevalence of continued dry weather prior to an outbreak of diphtheria, and in this case no doubt deficient flushing of drains is an important factor.—I am, Sirs, yours faithfully,

Surbiton, Aug. 26th, 1895. F. P. ATKINSON.

THE ANTISEPTIC SYSTEM.

To the Editors of THE LANCET.

SIRS,—Now that the benefits derived from antiseptic measures in practice are widely known and accepted it is desirable that a word of caution be uttered as to how far their uses are sometimes adopted unnecessarily and unjustifiably. Anyone who has followed the progress of the treatment of disease will admit that such measures have played a prominent part in the great forces of evolution, which for better or worse are inevitable. I have before me two instances taken from THE LANCET which exemplify the points above mentioned. 1. In THE LANCET of March 2nd, 1895, the following case is recorded:—A child aged three years was accidentally subjected to carbolic acid treatment, the acid being rubbed into the scalp for three minutes, being mistaken for the ointment, and producing unconsciousness in five minutes, followed by coma in one hour, which lasted five hours. 2. In THE LANCET of June 1st, 1895, the following cases are recorded:—(*a*) A boy aged fifteen years on Aug. 24th, 1894, was being prepared for an operation to take place in the evening. At 12 P.M. a carbolic compress was applied over the right thigh. At 2.30 A.M. the patient was found to be comatose. At 10 A.M. on the 28th he was still comatose. At 10.30 he partially regained his consciousness. On Sept. 1st he had recovered. On Sept. 3rd he was again subjected to a compress, an operation being in view; but, again suffering from the effects of the drug, the operation was postponed. (*b*) A boy aged six years and a half on Jan. 30th, 1895, at 12.20 P.M., had a carbolic compress (1 in 20) applied over the skin in the right iliac fossa. At 1.30 P.M. the child was noticed to groan and shortly afterwards found to be comatose. At 6 P.M. the child was recovering consciousness. At 7.30 P.M. consciousness returned, and the history states that he was a few days in regaining his original health. These last two cases, recorded in THE LANCET of June 1st, 1895, are instructive in pointing out the unjustifiable uses of the antiseptic system in subjecting patients of the ages of fifteen and six years respectively to the action of a common poison for two hours and one hour, when all that was necessary from an aseptic point of view could have been done five minutes prior to the operation by ordinary washing with soap and water, to be followed by bathing with some antiseptic solution. I believe there is no record of any case known where infection has taken place through a healthy and unbroken skin, and therefore it is reasonable to infer that any extraneous matter upon the skin likely to interfere with the success of the operation would not be found to penetrate beyond the epidermis. The writer talks about "peculiar susceptibility" of patients. There seems to be nothing peculiar, except that of surprise at not hearing of more such cases. And if by the use of the carbolic compress the full effects are sometimes reached, what relation will a milder dose bear to the state of anæsthesia? The unnecessary application of the "system" is also carried out in midwifery practice.

I am, Sirs, yours faithfully,

Chiddingfold, Aug. 24th, 1895. A. P. WALTERS.

"UNQUALIFIED PRACTICE."

To the Editors of THE LANCET.

SIRS,—I have observed in the pages of THE LANCET several letters regarding unqualified assistants. As this subject will yet, I believe, be taken up and dealt with by the General Medical Council, there is an aspect of the question which I hope that learned body will not overlook—viz., the advantages of an unqualified assistantship to the student of to-day who is the practitioner of to-morrow. Is not one of the defects of modern medical education that it is too theoretical? In this it does not excel or come up to the old apprenticeship days. A student does not gain at lectures or even in the hospital that experience so necessary to the general practitioner, and during his long holidays a medical student could not do better than gain a practical knowledge of drugs by dispensing, attend simple cases in surgery, and attend cases of labour. If he is trusted to do these in dispensary practice at college, why should he not be allowed to do so, perhaps to have a comfortable home during holidays while his resources are limited, or to assist some old practitioner whose means forbid him employing a fully qualified medical man? Of course, it is undoubtedly abused, but that is no argument against the practice.

I am, Sirs, yours truly,

Edinburgh, Aug. 27th, 1895. JAS. ANDERSON.

"THE PARASITE OF MALARIA AND MALARIAL FEVER."

To the Editors of THE LANCET.

SIRS,—In THE LANCET of July 6th you publish an article by Dr. G. Thin on the above subject, supplying to some extent the much wanted detailed information as to the methods of staining that organism. There are one or two points (which may be of interest) not mentioned: 1. In using eosine and methylene blue for its demonstration the test of a sufficiently well-stained preparation, to be of value as negative evidence, is that the eosinophil corpuscles must show as blue corpuscles with the eosinophil granules as sharply defined red without a tinge of purple. If they are blue the plasmodium will also be stained blue, but if the eosinophil granules are in the least purple the eosin in the red corpuscles will be to some extent replaced by methylene blue, and the plasmodium will be difficult to distinguish. 2. For the preparation of the vessels in the brain and other organs a simple, though rough, method is to take a small portion of the cortex and crush it between two cover glasses. These brain "squashes" can be fixed by heat or any other method and stained with

Digitized by Google

eosine and methylene blue and mounted in balsam. Most of the vessels still contain blood, and the results are at least quite equal to the plates in Dr. Thin's paper or in the Italian works, although there may be some distortion of the red corpuscles. 3. Anyone in doubt as to the existence of the bodies will find their presence most easily demonstrated in fatal cases, not necessarily in the most pigmented organ, the spleen, as that, though usually containing many intra-corpuscular bodies, may, although deeply pigmented (probably from the accumulation of pigment formed in other parts of the body), contain none, as in a recent case here where intra-corpuscular bodies were numerous in the cerebral vessels and none were found in the spleen, though this contained much recent pigment. As a rule, however, the spleen is the safest organ in which to look for them, unless the brain be pigmented. 4. It is much to be regretted that no certain and easy method of staining has yet been devised. The aqueous methylene blue has to be quite fresh, the mixed solution of eosine and methylene blue does not keep, and with Löffler's solution the eosine is too rapidly replaced. 5. Without staining too many mistakes occur. Vacuoles are easily taken for the plasmodium, and in much that has been written too little has been made of this liability to error. I am convinced that till some more certain but quick and simple method is found we shall have little help from the discovery of these bodies in differentiating the heterogeneous mass of tropical fevers.—I am, Sirs, yours faithfully,

C. W. DANIELS, M.B. Cantab.,
Pathologist to the Georgetown Hospital,
Georgetown, Aug. 8th, 1895. British Guiana.

"THE EXPLOSION AT THE MILE-END INFIRMARY."

To the Editors of THE LANCET.

SIRS,—Having supplied the press with a veracious account of the recent gas explosion in the grounds of this infirmary I cannot be responsible for the extravagant version published by some of the daily prints, upon which your annotation last week was, no doubt, based. The devastation described by those journals, I am happy to say, existed only in the mind of the contributor, and there was no wreckage of wards, no upheaval of corridors, no breaking of glass, and no panic among the patients whatever, and for the simple reason that the accident occurred in connexion with the gas company's mains quite outside the buildings. It is an unpleasant task to have to deprive the reading public of even a moderately sensational paragraph, but I feel bound, after the lecture you have read the management of this place, to repudiate the inference that there was any lack of supervision on the part of the staff. Without assuming an undue sense of security, I would venture to think that in an institution of this kind, which is manned the twenty-four hours round by a numerous staff of officials, such accidents as the overlooking of a breakdown in the gas supply are almost impossible for but a very short length of time. The possibility in future will, so far as we are concerned, be still further diminished by the adoption by our board of electric lighting throughout the infirmary which is in process of being carried out.

I am, Sirs, yours obediently,

A. H. ROBINSON,
Aug. 27th, 1895. Medical Superintendent.

VOLUNTEER MEDICAL SERVICE.

To the Editors of THE LANCET.

SIRS,—I beg to inform the Volunteer Medical Service through the columns of THE LANCET that my corps has been enabled to obtain permission, after representation to that effect, for regimental stretcher-bearers to wear a permanent badge on their right arm, showing their efficiency in their special instruction. The Geneva Cross hitherto worn has rightly been withdrawn, as regimental stretcher-bearers, being actually fighting men, could not adopt that badge without contravening the provisions of the Geneva Convention. Knowing that the Geneva Cross was much valued and that a badge would be appreciated, and that without some such mark the ambulance work in all regiments would languish and suffer, I made a special representation of the case to the authorities at the War Office, which was strongly backed by my colonel and the principal medical officer of the Home District. The result has been that last week we received an official letter stating that His Royal Highness the Commander-in-Chief had granted the request and that for the future all regimental stretcher-bearers might wear as a permanent badge of their efficiency a distinctive mark on their right arm, a sketch of which was enclosed. This badge consists of a circle of red round a ground of the same colour as the tunic, having the letters S.B. embroidered on it in red and blue, and in due course it will be adopted and ordered. I trust that this willing and ready desire to meet the wishes of the Volunteer Medical Service will prove satisfactory to all; and in concluding I desire to express my opinion that the new badge will in no way interfere with the adoption by all regimental stretcher-bearers, when actually employed as such, of the authorised brassard hitherto worn on the left forearm. I willingly express my thanks to Colonel Josselyn and Surgeon-Colonel Churchill, A.M.S., for the ready assistance which they have given to my application.

I am, Sirs, your obedient servant,

M. BAINES, V.D., M.D.
Surgeon-Lieutenant-Colonel 1st Middlesex Vol., R.E.
Headquarters, College-street, Chelsea, S.W., Aug. 25th, 1895.

"SPECIALISM IN MEDICINE."

To the Editors of THE LANCET.

SIRS,—Your correspondent "A Specialist" entirely misreads me when he supposes that I find fault with specialists for overcharging. I have always held that the amount of a fee honestly earned is a matter which rests entirely with the medical man and his patient. What I do complain of is that among certain specialists the fee is too often dishonestly earned. For what name other than dishonesty can be given to the growing practice, almost confined, I believe, to specialists, of subjecting patients after the most trivial operations to after-treatment considered totally unnecessary in the case of hospital patients, and of investing these minor operative procedures with all the gravity associated with a major operation, for the sole object of enabling a larger fee to be asked? To draw attention to this practice was the object of my letter published in THE LANCET of Aug. 17th. In it I took pains to illustrate the charge I laid by cases in point. From the fact that he ignores this I can only assume that "A Specialist" has become so accustomed to viewing life through special spectacles that he fails to recognise as dishonest acts which the ordinary man does not hesitate to pronounce such. If he reflects a moment, too, he will see that the practice in question is equally hard upon the general practitioner as upon the unfortunate patient—e.g., it has happened to myself, and, as I am aware, to many others, that patients for whom I have arranged to remove adenoids have been persuaded by friends to go to London to "see a specialist." On their return I have either been reproached for having represented the operation as being so very trivial, "scarcely more severe than the removal of tonsils," whereas they had been confined to a private hospital for a week or a fortnight with a nurse in attendance; or it has been assumed, and naturally, that I had not recognised the gravity of the case and that much more had been done in the way of operative treatment than I had intended to do. To the hackneyed arguments in favour of the multiplication of specialties which "A Specialist" puts forward I refer him for my answer to the clear and forcible remarks on the subject which have from time to time appeared in the leading articles of THE LANCET.

I am, Sirs, yours faithfully,

Aug. 27th, 1895. A GENERAL PRACTITIONER.

"OVER-OPERATING IN GYNÆCOLOGY."

To the Editors of THE LANCET.

SIRS,—I venture to trouble you on some aspects of the question of the so-called "over-operating" in gynæcology. What is "over-operating"? Does it mean the wilful undertaking of operations that the operator knows full well in his heart can be of no service whatever to the patient—operations undertaken solely for the purpose of putting money in the purse of the operator? If so, then such "over-operating" at once excites indignation and condemnation at the hands of all right-thinking men, of all honest men, and it is immaterial what the operator may call himself—obstetric physician, surgeon, gynæcological surgeon, or anything else. It is the

Digitized by Google

act that is wrong; the act is indeed a crime, and whoever is guilty of it deserves to be branded as a criminal. But perhaps this is not the meaning of "over-operating." It may mean operations undertaken by those who are in a position to act as pioneers, each in his own department. In this sense it merely means operations undertaken in the light of present knowledge that would formerly have been regarded as impossible. If it means this those who use the term mean that we should be content with the state of things at some particular moment and refuse to recognise that there may be more things in heaven and earth than are dreamt of in our philosophy. Anything that is unfamiliar and untried must be wrong; those who try to advance are guilty of "over-operating." In this connexion it is well to take example by the steam-engine, and to observe that what seemed a very high rate of speed to our grandfathers would seem a slow pace to those who travelled by either of the expresses in the recent "race to Aberdeen." The truth is that Sir W. Priestley and those who go with him are obviously opposed to the obstetric physician of the present day operating at all. To take an illustration from Æsop's Fables, they may be divided into: 1. The foxes who have had the misfortune to be born without tails—the obstetric physicians who have never done abdominal operations and never wish to see their successors do so. 2. Those who have had tails, and very fine ones too, but who for reasons of their own have deprived themselves of these useful appendages—the obstetric physician who has given up operating. 3. Those who, whether they would or not, have been deprived of their tails—those obstetric physicians who have done abdominal operations, but have, for one reason or another, been unable to continue performing them. The suggestion that an operator, because he may have removed a suppurating ovarian tumour, is therefore unable safely to attend a midwifery case will not bear a moment's consideration in face of the abundant evidence to the contrary; nor, indeed, can the obstetric physician who does not operate attend midwifery with any cleaner conscience or cleaner hands. For even the obstetric physicians who do not operate practise gynæcology, and in so doing contaminate their hands with all kinds of foul vaginal discharges, such as those in cases of cancer of the uterus; they also see and examine cases of puerperal fever in consultation. If they were consistent they would give up gynæcology altogether, and attend one midwifery case per annum, remaining the other eleven months in quarantine. Even then they might happen to meet and shake hands with an operating obstetric physician or surgeon on their way to their annual case—and so be undone. The whole thing is, however, ridiculous in the face of the teaching of experience; both obstetric physicians who do not operate and those who do are equally dependent on the efficacy of antiseptics, and the safety of their patients depends on the thoroughness with which they understand and perform personal disinfection. As it is, both in the obstetric world and in the animal kingdom, the majority of foxes have not lost their tails and do not intend to part with them, Sir W. Priestley and Mr. Malcolm notwithstanding.

I am, Sirs, yours truly,

Aug. 23rd. VULPES NON EQUIDEM SINE CAUDA.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

Is a Crematorium desirable?

THE question of the disposal of the dead is gradually making itself felt by the large populations in our midst. The aggregation in centres and the overcrowding in many places force attention to the dangers which arise and the difficulty in finding an adequate remedy. One deduction without doubt opens a way of relief for the disposal of the dead in a manner from which the living will not suffer. This is to be found in cremation. The results of the process at Woking and Manchester encourage the advocates of the system to believe that additional facilities for carrying it out would lead to progress in the cause. The vast number of inhabitants in this midland area have no provision at present for furthering their views in this direction in a practical form. Sanitarians and those interested in the subject will do well in calling attention to it and in endeavouring to make known the evils of interment in thickly populated places.

Opium and the Pharmacy Act.

A woman aged forty-eight years, whose death was the subject of an inquiry at the coroner's court, seems to have been in the habit of taking laudanum, which was obtained with great ease. An unqualified druggist admitted selling three drachms of the tincture of opium for twopence, and three hours afterwards another fourpennyworth to the same woman. This vicious habit of opium-taking is very common among the poor, the cheapness and readiness with which it can be obtained favouring the spread of the vice, and tending to draw more victims under its pernicious influence. Another instance of opium poisoning was heard the same day in a different court. An actor was charged before the magistrates with attempting to commit suicide. A large dose of laudanum was admitted to have been taken with the intention of destroying life. Prompt action on the part of the hotel landlord frustrated the design taking effect. The culprit was dismissed with a caution.

Ear and Throat Hospital.

An important era in this institution has been inaugurated by the opening of an in-patient department on the 12th inst. under the presidency of Lord Leigh. The hospital, which has been established for fifty years, has often felt the need of beds for the more immediate supervision and treatment of patients. The fact of 18,000 patients having been treated in the year 1894 is sufficient evidence of the necessity for some internal arrangements. At present there is space for thirty beds, though it is proposed to occupy only ten of these until the funds of the hospital warrant a greater number.

The Corbett Hospital, Stourbridge.

The annual meeting was held on the 26th inst. under the presidency of Viscount Cobham. The report showed that not only had the eighteen beds been filled, but that there had been great demand for additional room. Mr. Corbett again very generously had made provision for children to be admitted, giving £1000 for endowment and £500 for the necessary addition to ensure this. The total ordinary income for the year amounted to £980 16*s.* 2*d.*, and the expenditure to £1100.

Aston Flower Mission.

This is a flourishing little society for the sale of flowers given to the mission to purchase letters for the hospitals and to distribute these among the deserving poor. An interest is thus created in the sick, occupation is found, and human sympathies are widened and extended in a number of good ways.

Aug 27th.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

The Epidemic of Homicide and Suicide.

THE terrible frequency of crimes of violence ending fatally and of suicides which has been prevalent all over the country has been very marked in this city and neighbourhood. One very sad case, in which the child of a local practitioner was the victim and a medical assistant the alleged perpetrator, has been already noticed in THE LANCET. As the accused has been committed for trial it would be improper to comment upon the case beyond stating the fact that in this, as in most other cases, intemperance plays a very prominent part. It would be well if the well-meant efforts of temperance reformers could be so regulated that those who are in danger of becoming drunkards could be induced to be total abstainers; but it is necessary to differentiate. There are many who, though not total abstainers, are no more likely to become drunkards than total abstainers; they can use this world and the good things in it without abusing either; and it is a melancholy fact well known to medical practitioners that men and women who have been total abstainers up to middle life have become confirmed drunkards.

Teetotal Ships.

For more than half a century Liverpool, in common with other sea-ports, has made experiments as to the value of enforced total abstinence on a very extensive scale. Of the total number of ships leaving the Mersey the crews of the large majority have been required to sign articles "No grog allowed," and with few exceptions this rule has been rigidly

Digitized by Google

enforced. While it is gratifying to note that many seafaring men have been induced to become strictly sober, it must not be forgotten that "no grog allowed" is applied to the forecastle and not to the cabin. Poor Jack, who had to do all the pulling and hauling, and to endure the hardship of laying out on the yard reefing topsails in snow, frost, squalls, and rain, was compelled to be a total abstainer; the captain and officers, who had none of these duties to perform, but whose sobriety was of even greater consequence, might drink grog *ad lib.* This enforced sobriety does not prevent sailors from rushing to the public-house as soon as they land, and it becomes a very grave question whether a reasonable amount of stimulant on board ship might not tend to promote sobriety ashore.

Coffee as a Stimulant and Article of Diet.

Alluding to the annotation in the last issue of THE LANCET on "A German School of Cookery," it is to be lamented that good, wholesome, pure coffee, free from chicory, is not brought to the notice of the public by advertisers as much as tea, cocoa, or chocolate is. Those who have travelled on the Continent know that a cup of excellent coffee can be obtained at an almost trifling cost, and know what an excellent stimulant it is. Why should this be? and why, on the other hand, should coffee, even in the homes of the rich in this country, be too often wholly undrinkable? That there is no difficulty about the making of good coffee is proved by the fact that the best is made in the simplest apparatus—a plain earthenware jug. This, with boiling water and a reasonable amount of berries freshly ground, is all that is required. Both the demand and supply of coffee in this country are diminishing, but a more extended knowledge of its value as a stimulant and as an article of diet would ensure its increased use and in due time its reduced price.

Greater Liverpool.

The extension of the city boundaries is now all but an accomplished fact. Many advantages will be gained, not the least of which will be a more accurate computation of the real population of the city and a fairer estimate of its death ratio. When the healthy suburbs, in which so many of the citizens of Liverpool actually live, are comprised it is more than probable that the mortality of Liverpool will compare favourably with that of any large town or city.

Aug. 27th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Meeting of the British Dental Association in Edinburgh.

THE annual general meeting of the British Dental Association is to be held in Edinburgh on Thursday, Friday, and Saturday of this week. Rooms have been obtained for the meeting in the University. Demonstrations are to be given both there and in the Dental Hospital and School, Chambers-street. Mr. W. Bowman Macleod of Edinburgh is the President-elect. As is usual at such gatherings, the social element has not been omitted. On Wednesday night there is to be a smoking concert in the Waterloo Hotel, on Monday the Lord Provost and magistrates will give a reception at the City Chambers, on Friday the annual dinner of the Association is to be held, and Mrs. Bowman Macleod will give a ladies' reception in the evening at the Waterloo Hotel.

Bazaar for St. Andrews University Students' Union.

A bazaar to pay off the debt on the St. Andrews University Students' Union was held on Thursday, Friday, and Saturday of last week. On Thursday it was opened by the Marquis of Bute, on Friday by Lady Helen Monroe Ferguson, and on Saturday by Principal Donaldson. The result has been most satisfactory, for the takings for the three days amounted to £1370, which is sufficient to pay off the debt, leave a sum for endowment, and a small sum as the nucleus of a fund for a union and reading room for the lady students.

University of Glasgow.

Professor Joseph Coats and Dr. L. R. Sutherland are to conduct during the month of September a post-graduate course for practical instruction in the methods of pathological research. A similar course conducted last year attracted a large number of the younger graduates, who highly appreciated the thorough and practical method of the class. At Queen Margaret College the following lecturers have been appointed: Dr. Charles Workman to the lecture ship in Pathology and Mr. J. Hogarth Pringle to the lecture-ship in Surgery. The instruction of the women students in clinical medicine is to be undertaken by Dr. J. Lindsay Steven, physician to the Royal Infirmary, and he is to be assisted by Dr. W. K. Hunter, who has recently been appointed extra physician to the dispensary of the infirmary.

Glasgow Maternity Hospital.

Two vacancies will shortly occur in the staff of this hospital, Professor Murdoch Cameron retiring from the position of Obstetric Physician and Dr. Malcolm Black from that of Assistant Obstetric Physician. The new appointments are not to be made until November, yet several candidates are already in the field.

University College, Dundee.

Dr. John Yule Mackay, Professor of Anatomy, has been requested to act in conjunction with the chairman of the council in discharge of the duties of the Principalship during the present vacancy.

Aberdeen University: Death of Mr. Charles Mitchell, LL.D.

A great gloom has been cast over the University and the city by the announcement of the death, on Thursday, Aug. 22nd, of Mr. Charles Mitchell, LL.D., the greatest benefactor of the University in modern times. In a month he was to have been the central figure at a great inaugural celebration, at which the magnificent buildings, so closely associated with his name, were to have been opened. Mr. Mitchell, who was in his seventy-fifth year, was a native of Aberdeen, and began his professional life as an apprentice to an Aberdeen firm of engineers. He studied chemistry at Aberdeen University, and had the distinction of being first prizeman in 1840. He left Aberdeen in 1842, but after the lapse of half a century and more, during which time he had amassed a large fortune and pushed his way to the head of the famous Newcastle firm known as Sir W. G. Armstrong, Mitchell, and Company, he still retained the warmest interest in and affection for the city and University that started him in his prosperous and useful career. The glorious Mitchell Tower and splendid Graduation Hall and Students' Union are a standing memorial to his wisdom and generosity. It may almost be said that but for his munificence and the deep interest he showed in the work, the great extension scheme at Marischal College would have come to a deadlock. I copy from the *Free Press* the account of his bequests to the University: "When the Extension Movement was initiated in 1891 Mr. Mitchell immediately responded with a donation of £1000. In the following year he supplemented this by an offer to erect a Graduation Hall and Students' Union, estimated to cost together £13,000. This generous offer, handsome in itself, has since been supplemented by Mr. Mitchell by the provision of a grand organ; by filling (at a cost of £2500) the large window in the Graduation Hall (to be known as the Historical Window) and ten side windows with stained glass commemorative of donors to the University (both King's and Marischal Colleges), the leading principals and professors, and the most distinguished graduates; by laying an oak floor in the old hall of Marischal College (now to be constituted an art gallery); and by supplying the requisite furnishings of the Students' Union. In addition to all this Mr. Mitchell undertook the cost of the heightening of the tower of Marischal College, according to the design of Mr. A. Marshall Mackenzie, A.R.S.A., the architect—a cost estimated at £7000. Quite recently Mr. Mitchell undertook to further complete the artistic effect of the summit of the tower by adding four small turrets, by putting in a clock and bell (estimated to cost £300), and by filling the bay windows of the old portion of the tower with stained glass. Mr. Mitchell also gave £1200 for the purchase of a house in Queen-street to assist in the scheme of extension. Still more recently, we understand, he intimated his intention of contributing £6000 towards the erection of the south wing of the extension scheme, and of the terminal towers of the south and north wings, on condition of the other £10,000 required being subscribed, and even made provision for this being carried out in the event of his decease." He must in all have contributed something like £31,000 to the scheme, and his invaluable assistance and advice enabled many difficulties to be surmounted. In February, 1893, the Senators conferred on him the honorary degree of LL.D., and the tower and Graduation Hall are to be named after him.

Digitized by Google

In the altered circumstances the arrangements made for the great celebration next month now no longer hold. Immediately on receipt of the sad news Sir William Geddes, the Principal, telegraphed to Mr. Mitchell's son: "Deeply concerned at most sad tidings. Aberdeen University mourns her generous and noble-hearted son. We beg to offer heartfelt sympathy." The Celebration Committee met and came to the following resolution: "That, in consequence of the sudden and lamented death of Dr. Charles Mitchell of Newcastle, who has been the chief promoter of the extension scheme, and in whose honour the proposed autumn celebration was chiefly designed, the Ceremonial Committee suspends its deliberations until such time as the wish of his family and the resolutions of the Court and Senatus consequent on the altered circumstances are ascertained." A meeting of the University Court is called for Tuesday next to consider the course of action to be taken in reference to the inaugural celebration. Principal Sir William Geddes, the Lord Provost, and Professor Niven travelled through to be present at the funeral service in St. George's, Jesmond, on Monday, Aug. 26th, and a memorial service was held in the West Church, Aberdeen, during the time of the funeral. The great bell Victoria in St. Nicholas Tower tolled from 11 till 11.30, at which hour the funeral was taking place at Newcastle, and representatives of the town council, the University, the school board, and the trades marched in procession to the church, in which also were assembled a large number of the general public.

Health of Aberdeen.

The zymotic diseases notified to the medical officer last week were: Measles, 5; scarlet fever, 12; typhoid fever, 1; whooping-cough, 41; erysipelas, 1; puerperal fever, 1; membranous croup, 1; total, 62, being 10 cases more than for the preceding week.

Aug. 28th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Addresses from the Royal Colleges of Physicians and Surgeons, Ireland, to the new Lord Lieutenant.

ON Monday afternoon his Excellency the Lord Lieutenant received in the Throne-room, Dublin Castle, addresses from the Royal College of Surgeons and the Royal College of Physicians of Ireland. His Excellency was accompanied by the Countess Cadogan and the Hon. E. Cadogan, and attended by Sir William Kay, C.B., private secretary; Mr. Arthur Vicars, Ulster King at Arms; Mr. John Olphert, D.L., Gentleman Usher; Colonel Deane, Chamberlain; and Captain Fielding, A.D.C. in Waiting. The deputation from the Royal College of Surgeons of Ireland, which consisted of the President, Vice-President, and Council, was first introduced, and was most graciously received by his Excellency, who, in reply to an allusion by Sir William Thornley Stoker to the increasing importance of the educational work done by the College since it was incorporated under Royal Charter in 1784, made use of the following words: "I am aware that your schools of surgery have attained a high standard, of which you may be justly proud, and that they possess a reputation which extends to the most distant quarters of the civilised world." The address from the Royal College of Physicians of Ireland was presented by the President, Dr. Walter G. Smith. His Excellency the Lord Lieutenant, in his reply, seemed especially pleased by the reference which the address contained to the prominent position which some members of his ancient family had occupied some two centuries ago in Ireland.

St. Patrick's Home for Trained Nurses, Dublin.

A special service was held in St. Patrick's Cathedral on Sunday in aid of the St. Patrick Nurses' Home. Dublin is now crowded with visitors, both clerical, medical, and lay. His Grace, Lord Plunket, Archbishop of Dublin, addressed an unusually large audience on the occasion.

Royal Hospital Saturday, Belfast.

The street collection in aid of the Royal Hospital will take place on Sept. 14th. The Lord Mayor and the executive committee are putting forth every effort to make the movement this year a decided success.

Ulster Eye, Ear, and Throat Hospital.

At a meeting of the board of management of this institution on Aug. 20th the plans for the extension and improvement of the hospital as finally settled were approved of. The changes will cost £1300, the whole of which is in hand. On the advice of the surgeon, Dr. McKeown, it has been decided that one of the rooms in the extension should be made a special operating-room for delicate operations, such as cataract, and be fitted up in accordance with the requirements of aseptic surgery. It will cost about £65. The extension, amongst other things, will comprise four bath-rooms and closets, two day-rooms for male and female patients, improved accommodation for nurses and servants, additional ward accommodation, the special operating-room, and a laundry. It is hoped that the extension will be completed, or nearly so, in January, 1896, which will be twenty-five years after the foundation of the hospital.

Carnlough Water and Sewerage Scheme.

It is now hoped that this scheme will be pushed on to completion, as the Larne board of guardians have received from the engineer the plans, specifications, and estimate. These will be forwarded to the Local Government Board for their approval, and the water is to be analysed by Professor Hodges of Queen's College, Belfast. The cost will be met, it is proposed, by a loan to be repaid in instalments spread over fifty years.

Glenarm Water-supply.

Mr. L. O'Connor, medical sanitary officer of Glenarm, reported to the Larne board of guardians at their meeting on Aug. 21st that the water-supply is becoming quite inadequate owing to the quantity of water used in the hotel yards for cleaning and watering horses; and he recommends that the drivers of horses should be made to take the horses to the river and not to use the town supply. Glenarm is a centre towards which an immense deal of tourist traffic goes in the summer, and hence the waste of water at the hotels for the horses. The board decided to place one-inch meters on the supply of the two hotels.

Water-supply and Sanitation in Portrush.

A Belfast gentleman staying at Portrush wrote to the Local Government Board a strong complaint regarding the water-supply of Portrush, which he held responsible for an attack of gastric fever to which his son had been subjected. He also alleged that fever was rife in that town. This letter was transmitted to the local authorities, and a report on the matter was presented on Aug. 24th, at a meeting of the Coleraine guardians, from the Portrush Water and Sanitary Committee, in which they say that their medical officer, Dr. Martin, has carefully investigated the whole question and can find but three cases of illness reported, only one of which was under his care. This was a case of gastritis which did not originate in Portrush, as it was brought from a distance. The second case was one of water on the brain; and the third case, that of the son of the gentleman who wrote to the Local Government Board, was not brought under Dr. Martin's notice. The committee are satisfied from the statements of their medical officer that there has been no case of epidemic disease in Portrush this summer, and that the general health of the town has been exceptionally good. The Board of Works having now granted the loan requested for the extension and improvement of the water-supply, the works will be proceeded with without further delay, on the completion of which an ample and pure supply may be relied on.

Garvagh Dispensary.

I am very glad to be able to announce that the Coleraine board of guardians have decided unanimously to grant Dr. McNeary, the retired medical officer of Garvagh Dispensary, the full amount of superannuation which by law they are empowered to give. Dr. McNeary is now sixty-nine years of age. Since 1852 he has been in the service of the guardians, and only on one occasion has he, as a member of the board pointed out, put them to the expense of a locumtenent, when, through hard work and exposure, he contracted a cold which resulted in paralysis and subsequent incapacity for three months. Two-thirds of his salary will amount only to £88 12*s.* 11*d.*, not a large retiring income after such a lengthened service.

Crumlin Dispensary.

Mr. J. H. Carson of Portrush has been appointed dispensary medical officer of the Crumlin district. His golfing friends in Portrush, where he was a member of the council of the Royal Golf Club, have presented him with a valuable gold watch and chain.

Digitized by Google

Royal Hospital, Belfast.

At the quarterly meeting held on Aug. 26th, it was reported that during the past quarter 452 intern and 6038 extern patients were treated. Dr. Calwell has been appointed physician to the chest department in place of Dr. S. Smith (resigned). Financially there is an excess of expenditure over receipts for the past eleven months of £978 1*s*. The following members of the staff, who retire by rotation, were re-elected:—Dr. Ross (physician), Dr. J. Walton Browne (surgeon), Professor Byers (physician for diseases of women), Dr. Nelson (ophthalmic surgeon), and Dr. S. Smith (assistant physician). Dr. Lorrain Smith was appointed pathologist.

The Battle of the Clubs at Cork.

Last week I wired you the result of the conference which was held at the instance of the Mayor for the purpose of arranging, if possible, the dispute between the Cork profession and the clubs. I now propose to give you a few further particulars which may prove interesting to many of your readers. At the commencement of the proceedings one of the club delegates thought he would overawe the medical representatives by delivering a speech in which he declared that the rules formulated by the profession had been ignored by the clubs, and that prior to any exchange of opinions the rules should first be withdrawn. One of the medical delegates replied, firmly declining to withdraw the rules, and expressing regret that the previous speaker should think it necessary to assume the attitude he had. The medical delegates, he added, had come there on the invitation of the Mayor to discuss the matters in dispute calmly and even amicably. The Mayor agreed that it would be much better to interchange opinions without any undue heat. The rules were then taken up seriatim. There was considerable discussion on the one which provided that the charges for medical attendance on a member and his family, without medicines, should be 7*s*. 6*d*. when the income was under £100 a year, and 15*s*. when over that sum and under £200 a year. The club delegates stated that in some of the clubs it would be impossible to adopt a sliding scale of the kind for members, and said that in many instances even by having reference to the valuation of members' houses it would be difficult to ascertain their incomes. The medical men had all along been conscious of these difficulties and they were prepared to consider favourably the proposal that if the sliding scale were not insisted on the clubs would be willing to pay any reasonable remuneration. Again, the club delegates would agree to refuse admission to candidates in receipt of over £200 a year, but urged that existing members, no matter what their incomes, should be allowed to continue members of the clubs. As a great number of, I should say, opulent citizens joined the city clubs during the past ten years this proposition would require considerable discussion at the hands of the profession. The rule fixing the limit of distance at two miles the club representatives would modify by naming three miles, with the proviso that a member residing beyond two miles should pay car fare. They agreed to the rule that if a member of two clubs should require the services of the two club officers in consultation he should pay consultation fees to the second club officer. They also made no objection to the rule that a club officer should be at liberty to charge a fee if called to attend a member's wife within eight days after her confinement. It is evident that, as I have already mentioned, the crux of the whole situation was the question whether the medical men of Cork should meet in consultation the three imported officers, and last week I explained to you that loyalty to the Cork medical men who had previously been club officers would prevent the Cork profession from falling in with such an idea. An incident which has been freely commented on is worth referring to. One of the imported officers told the Mayor that he (the officer) should insist on a witness being present at the interview. The Mayor, equal to the occasion, retorted by asking him if he reposed so little confidence in the Mayor of Cork. This *contretemps* was all the more regrettable as both the medical and club delegates bear willing testimony to the impartiality, tact, and courtesy displayed by the Mayor throughout. As to the result of the three conferences I am distinctly of opinion that they were decidedly favourable to the profession. The medical delegates presented their case so incisively and at the same time with such calm dignity that a marked impression was evidently produced, not only on the Mayor, but also on the club delegates. One of the latter, who was most uncompromising at the beginning, was markedly conciliatory at the end of the proceedings, and expressed the hope and belief that the clubs would not introduce any other strangers into the city. In reviewing the present situation of affairs I would reiterate the grave warning given to the clubs by the Mayor. If an epidemic should break out in the city it may prove most serious to the clubs. The problem to be solved is, Can three medical men efficiently discharge duties heretofore performed by about a dozen? The universal opinion amongst the Cork practitioners is that victory is on their side, and that, to use a sporting phrase, they are winning "hands down." Time fights for the Cork men. Theirs is a waiting game, and I have no doubt success to a just cause is within very measurable distance.

Aug. 25th.

ROME.

(FROM OUR OWN CORRESPONDENT.)

Spermin and the Balneary Cure of Rheumatoid Arthritis.

YEAR by year the purely eliminative treatment of gouty and rheumatoid affections by thermo-mineral waters, whether in the form of bath or of beverage, has proved its insufficiency unless reinforced by concurrent measures preventing or antagonising the accumulation of uric acid in the circulation. Severely regulated diet is one, and not the least effective, among these supplementary modes of treatment; but even this—not always practicable, be it said, under the conditions of hotel life abroad—is not enough, and even by itself stands in need of supplement. The agent desiderated had been thought to reside in spermin ($C_5H_{14}N_2$), an organic base found in proportionally greater quantity in the testicles, in the prostate, the thyroid, thymus, and pancreatic glands, and in the spleen and ovaries, as well as in the blood. Investigation has subsequently elicited the fact that this body, so widely diffused in the organism, has a general physiological importance, enabling it to perform an essential part in what German biologists call "Gewebsathmung" (histological respiration). In solution it possesses the property of effecting and promoting physiological oxidation in and through the tissues—acting, in short, as a ferment in furtherance of the intra-organic oxidation referred to. Under normal as well as abnormal circumstances (it is known) the regressive metamorphosis of the albuminoid substances in the tissues yields a number of products, among which leucomaines, in the larger sense, play an essential *rôle*. These leucomaines represent all azotised products of the regressive metamorphosis whose oxidation stops short of urea, products classified as "intermediary," and their accumulation in the tissues (causing the "Autointoxicationen" of German pathologists) evolves, according to the place and character of each individual tissue, diseases of the most complex type, diseases constitutional and nervous, and of themselves predisposing to not a few infective maladies. Among these diseases arthritis urica has a place of its own, in which the imperfect oxidation that underlies it is susceptible of completion, till from the "intermediary" the product reaches the normal condition, and ceases to play the toxic part of its earlier stage. A stimulating, or rather tonic, agency effecting this metamorphosis has undoubtedly been found in spermin, only, however, in solution and as prepared on the principles laid down by its strenuous advocate, Professor Alexander Poehl of St. Petersburg. His paper in the *Zeitschrift für Klinische Medicin*[1] entitled "Einwirkung des Spermins auf den Stoffumsatz bei Autointoxicationen im Allgemeinen und bei harnsaurer Diathese im Speciellen" (Influence of Spermin on Metabolism in "Auto-intoxications" in general and on the Uric Acid Diathesis in particular) has made a profound impression on the balneological medicine of Italy, particularly as illustrated or confirmed by the series of cases (arthritis deformans, among others) in which its efficacy has been proved. With such an adjunct to his therapeutic armoury, aiding the action of the thermo-mineral waters, and reinforced, when indicated, by the "interrupted current," while favoured by a judiciously regulated dietary, the balneary physician approaches even

[1] Band xxvi., Hefte 1 und 2.

Digitized by Google

inveterate cases of rheumatoid arthritis with much less of the diffidence, not to say despair, of his predecessors. At the largely frequented waters of the Swiss Baden (Canton Aargau) spermin has been growing in favour with the profession, and its use in Italy has, I know, been sufficiently practised to vindicate for it the fair trial for which Professor Poehl so justifiably pleads.

Endemic Idiocy.

What pellagra is to the Lombardo-Venetian territory cretinism is to the southern slopes of the Alps, particularly in the province of Cuneo, the neighbourhood of Aosta, and all about Sondrio. France, too, has her not inconsiderable share of the scourge, which in her case, also, haunts the mountain regions—120,000, indeed, is the estimated cretin population of the Savoy, the Higher and Lower Alps, Arriège, the Jura, the Vosges, Aisner, the Maritime Alps, and even the Higher Pyrenees. Fully developed specimens of the cretin, moreover, are found in the Austrian Alps, the Carpathians, the Caucasus, and even in Thibet and the Andes. But the Alta Italia is the true traditional *nidus* of that form of "endemic idiocy" in its most marked and incorrigible type, dating from classic Roman times and evoking from Juvenal the exclamation: "Quis tumidum guttur miratur in Alpibus?" But if its presence has been so long familiar, its etiology remains obscure, still baffling the research of local and foreign investigators. Drinking-water deficient in iodine is assigned as one cause, while Mantegazza finds it in a combination of insanitary conditions—scanty ventilation, insufficient light, persistent humidity of the soil depending on special geological formation, and, above all, the unfavourable hygiene implied in the occupation of dwellings little better than caves embedded in mountain ravines and shut out from the genial sun. Of course, concurrent causes have their place in its development if not in its genesis, heredity and alcoholism among the number. A diet exclusively vegetable has also been suggested as one of these; but no explanation satisfactory to science has yet been found for a phenomenon of which we can only say with certainty that, as malaria is coincident with, if not consequent upon, deep-seated glandular disturbance manifested in hypertrophy of the spleen, so cretinism is associated with abnormal development of the thyroid; and that as malaria is favoured by marshy exhalation, so cretinism is at its worst when its victims respire the unrenewed air of confined mountain valleys and drink a water possibly deficient in alterative constituents, and assuredly deprived of the influence of the sun's rays. Such at least is the conclusion indicated by Dr. M. Gioberti in his researches through the Aosta ravines—a conclusion, I may add, not yet checked, as in the case of malaria, by investigations resulting in the detection of a pathogenic micro-organism. Klebs, it is true, some twenty years ago, announced his discovery of *naviculæ*, or special bacilli nestling in the alveoli of the thyroid; bacilli also were found quite recently by Maggi in the water conveyed by the town council of Milan from the Brembo—an Alpine source. But these results have not obtained even the provisional plausibility of those claimed by the discoverers of the malaria microbe; and pathology, for the present, declines to commit itself further than this: that (in the language of Dr. Stura, whose interesting paper is the most recent on the subject) "the goitrous agent affects the cortical substance of the brain, and that the thyroid gland, by hypertrophy, compensates in some measure the pernicious action of the cretinogenous germs up to a given point, beyond which cretinism supervenes by cerebral poisoning. Something similar happens in and through the spleen and liver in the majority of infective maladies, miasmatic as well as contagious." Removed from his native surroundings, the cretin, when not too late, does lose some of his degenerative characteristics; but as a rule these are far too inveterate even for mitigation. The dwarfish stature; the wrinkled, semi-bestial countenance, partaking of that of childhood and old age; the flat nose, *retroussé* and compressed inwards at the root; the blubber lips, and tongue generally protruded and viscous with tenacious saliva; the small eyes, now protuberant, now sunken; the swollen eyebrows; the motionless, stolid look; the soft, pasty, livid integument, with the nails enormously hypertrophied; the thyroid many times its normal size; the head squat and depressed at the vertex and temples, while gibbous at the occiput, and always out of proportion to the body; the hair luxuriant, but shaggy, and falling naturally into wisps; the breast caving in; the fingers thin and elongated, with articulations scarcely perceptible; the soles of the feet large, sometimes curved in pithecoid fashion—such are the physical marks, having their physiological analogue in a languor of all the functions except that of the stomach, though even this has little discrimination as to food, and will on occasion satisfy itself with earth or chalk, or the "pica-*menu*." The cretin lives like an animal, lolling on the highway, generally in the sun when he can get it, or when he attempts to walk, yawing, with pendulous arms, like a drunken man, irrespectively of obstacles or dangers. His life is mercifully a short one, like that of most idiots—the brain being seldom equal to more than instinctive acts, often predatory or inclining to habits mostly evil. Of course, from this type of the absolutely brutish creation there are deviations for the better, in which improvement is possible even to the extent of agricultural labour, sometimes of reading and writing. But ameliorative effort is all too ineffective, and the rehabilitation of the cretin remains among the opprobria of medicine. "It will yield only," says Dr. Stura, whose admirable paper has suggested not a few of the above details, "to the great prophylactic means indicated by hygiene ..... removal of individual cretins from affected localities. This method, the most rational, is unfortunately the most difficult to put in practice. ..... Emigration, facilitated by railway communication with the valleys afflicted with the endemic, would be most advantageous. Very useful would also be improvement of dwellings, pure water-supply, and regeneration of the soil." All these, however, are but general rules for dealing with a phenomenon which, as the product of a violated hygiene, must be counteracted by a reassertion of hygienic law till, as savage beasts inimical to man and civilisation are disappearing from the world's fauna, so cretinism, like other monstrosities, will shrink in prevalence and character and become a memory, preserved in museums, of an ill-regulated and unregretted past.

(FROM OUR OWN CORRESPONDENT.)

Death from the Electric Current.

AT a recent meeting of the Styrian Medical Society Professor Kratter read a paper on the case of a workman who was killed by a shock received whilst he was occupied in straining telegraph wires. Post-mortem examination, performed twenty-one hours after death, showed a ruptured blister on the left forefinger, marked rigidity, and intense ecchymosis on the dependent parts of the body. There were also hypervenosity of the blood, venous engorgement of the lungs, extravasation of blood into the common sheath of both the carotid arteries and the vagus nerve, and symmetrical hæmorrhages along the spinal cord. If an electric current of 1500 volts acts upon rabbits some of the animals live, and others show typical symptoms such as tetanic contraction of all muscles and instantaneous stoppage of the respiration, the heart nevertheless continuing to act. There may also sometimes be found disorganisation of the brain, with destruction of the peripheral parts of the cortex and intra-cranial effusion of blood. The stoppage of the respiration lasts half a minute. From these experiments it results that the first effect consists in permanent or temporary arrest of the respiration. Death from electric shock is, therefore, a form of suffocation, and persons who meet with such an accident are to be treated by artificial respiration, as in ordinary cases of suffocation.

A Follower of Tolstoi.

Dr. Skarvan, who has until now been on six months' service with the Austrian Medical Staff, has been tried by court-martial on charges of insubordination and expressing opinions subversive of discipline. Being a true follower of Tolstoi, he was fascinated with the utopian schemes of the Russian reformer, and supported his theories in a letter addressed to the commander of the garrison hospital, wherein he pointed out that military service is incompatible with humanity and announced his intention of disregarding authority. The court unanimously found the charges against the prisoner proved, condemned him to three months' imprisonment and to the loss of his diploma, and forbade him to practise his profession in Austria-Hungary or in the States connected therewith by treaty. The matter cannot, however be allowed to end here, for although the court-martial

Digitized by Google

may be empowered to punish Dr. Skarvan, it is in nowise authorised to cancel his diploma, which he while a civilian obtained in Innsbrück. This case has not failed to cause a great sensation throughout the medical profession.

Equinia in Man.

Dr. Honl has recorded a case of equinia in the *Klinische Rundschau*. The patient is thought to have contracted the disease while treating a horse affected with nasal catarrh of a suspicious type. He had numerous abscesses, and under his left knee-joint there was a diffuse, fluctuating, painful swelling; there was no discharge from the nasal passages, but there was a slight swelling of the nose and some erosion of the right tonsil and the soft palate. At the post-mortem examination hæmorrhages on the pleura, deficient expansion of the lungs, and brittleness of the cardiac muscle were found. Microscopical investigation showed leucocytes and bacilli. The discharge possesses a characteristic reaction, for when it is injected into the abdomen of a male guinea-pig swelling of the testicle occurs within twenty-four hours, and a culture of the bacilli may be found between the tunica albuginea and the other tunics of the testicle. The disease is communicated to man by the discharge coming into contact with a recent wound or with the mucous membrane of the nose, mouth, or conjunctiva. Sero-therapy will doubtless be the future treatment of equinia, for by injection with serum Cheneau and Pick have succeeded in preserving guinea-pigs from infection.

Serious Effects of Serpent Venom Absorbed through a Wound of the Mouth.

Dr. Hirschhorn has published the case of a man who suffered from the effects of serpent venom after sucking the wound of a girl who had been bitten by a viper. The girl recovered within a week, but the man had a painful swelling of the left submaxillary region extending to the neck, the chest, and the upper extremity, and he suffered also from vertigo, inability to stand, and clonic and tonic spasms of the left side of the body. The seizures lasted from half an hour to three hours, and after they ceased the skin assumed a reddish colour with blotches elevated above the general level. This exanthem resembled urticaria and caused a sensation of itching, disappearing after two hours. The spasms and the aura ushering in the paroxysms suggested epilepsy, but there was no unconsciousness. Examination showed that the inoculation had taken place through the gum, which was lacerated in consequence of the extraction of a tooth. Dr. Hirschhorn supposed these paroxysms to be toxæmic; bromide of potassium was administered, and the patient is at present free from them.

EGYPT.

(FROM OUR OWN CORRESPONDENT.)

Statistics of Kasr-el-Aini Hospital.

THE total admissions for 1894 were 4090, and an analysis of 690 cases admitted into one of the two medical sections of the hospital is interesting as throwing some light upon the relative frequency or rarity of well-known diseases. 19 men were admitted with typhus fever and 1 with relapsing fever; but, on the other hand, as in former years, there were no admissions from enteric fever. This racial difference, seen also in India, has yet to be satisfactorily explained, for unfortunately typhoid fever is common among Europeans. Intermittent fever accounted for 32 cases, and 6 others had enormous malarial spleens and ascites. Ankylostomiasis was diagnosed in 119 men and 6 women, and pellagra was present in 27 men and 1 woman, while bilharziosis was recognised in 20 men and 1 woman. Abscess of the liver was diagnosed in 9 men and also in a tenth which proved to be a suppurating hydatid; but cirrhosis of the liver, generally dependent on some cause other than alcohol, was found only in 4 cases. Aneurysm of the aorta occurred in 1 man; this, like other aneurysms, is rare in Egypt. Parenchymatous nephritis was present in 19 men and 10 women, but the granular form is rare, as might be expected in a country where alcohol and gout are little known. Cerebral hæmorrhage occurred in 5 men and 4 women, but it must be remembered that syphilis is not treated among the lower orders who fill the hospital wards. 2 men had locomotor ataxy, 7 had disseminated sclerosis, and, curiously enough, 3 had general paralysis. This last is a disease which is rare in this country as in most others where civilisation is not far advanced and where the population lives chiefly on cereals. It is regrettable to notice that 11 men and 2 women were admitted drunk, and there were also 4 cases of datura poisoning, besides 1 of hasheesh poisoning and 1 of mercury poisoning (an attempted suicide). The datura poisoning again reminds one of India. The story is always the same. A country man meets a town dweller who is travelling in his direction and who after some conversation proposes that they shall rest in the shade and eat their meal together. Sooner or later the townsman produces a cake or sweetmeat, and the bumpkin remembers no more until he finds himself in a hospital robbed of his money and goods.

The Government Hospital at Alexandria.

This hospital, with 180 patients, has changed so much for the better since 1884 that it can hardly be recognised. Roads have been made, the surrounding ground levelled, gardens laid out, and various pavilions erected. One is for infectious patients and another for sterilising the goods of the whole town, which are sent there in three special carts; while a flying ambulance does the necessary work at the patients' homes. During the month of May, for instance, 902 articles were disinfected, coming from 32 cases of infectious disease, and 49 private rooms were disinfected. A welcome legacy has been expended in building a kiosque where all water for hospital use is filtered by means of the block system. The consequence is that the patients of this hospital have at present a purer water-supply than any provided by the municipality.

Alexandria Water Company.

During the last eighteen months the attention of the municipality has been directed to the improvement of the water-supply of the town, and their efforts have been considerably aided by the able reports of Dr. Bitter, their sanitary inspector, who has had the advantage of being trained under Professor Koch. Assuming that the population of Alexandria is now 250,000, he has shown that the rich get an average of 500 litres of water daily, while about three-quarters of the people have to be content with only two or two and a half litres a day. Moreover, the poor have the privilege of paying for their water at a rate which is forty-six times dearer than the subscription levied on the rich. Until a year ago the intake was direct from a branch of the Mahmoudieh Canal, the banks of which were exposed to every sort of pollution in which the Oriental delights. This stream is now walled or pallisaded in on both sides, an improvement suggested by all sanitarians since the early days of the English occupation; but the quality of the water is, of course, of principal interest. In 1883 Professor Koch found that the so-called filtered water as supplied by the Alexandria Company contained several thousands of germs in a cubic centimetre. In 1894 Dr. Bitter's report was equally unfavourable. To-day the analyses show that both the canal water at the intake and the company's water as supplied to the consumer contain on an average 1500 germs per cubic centimetre. It may be said that in the spring of this year the water company supplied as many as 10,000 micro-organisms in the cubic centimetre; and yet the mortality for the first four months of 1895 showed a diminution of 1500 in comparison with the same period in 1894. It having thus been shown that the company's filter beds were practically of no value and could never supply the ideal water containing always less than 100 germs in the cubic centimetre, Alexandria naturally became desirous of having water at least as good as that supplied to Cairo, where the filter beds are greater in area and better constructed, and where the filtering process is carried on much more slowly. Dr. Bitter's proposal to erect sample filters as an experiment was accepted, and £1200 very generously voted to pay expenses. Since last September three systems have been on trial, and every day a bacteriological analysis has been made of the water of each filter. The block system, and another by which the water is first purified by Anderson's process and then by ordinary sand, yield the best results as to quality, showing only some thirty to fifty germs per cubic centimetre, but it is doubtful whether the necessary quantity could be supplied in the given time. It is possible, therefore, that the company may have to fall back upon sand and gravel as forming the best bed under the circumstances. The company, which is an English one and has a far-reaching monopoly, is fortunately willing to accept the advice, but no always the proposed reforms, of the sanitary inspector.

Cairo, Aug. 19th.

Obituary.

JOHN SYER BRISTOWE, M.D., F.R.C.P. LOND., M.R.C.S. ENG., LL.D. EDIN., F.R.S.

By the untimely death of Dr. Bristowe the medical profession has suffered a loss which is likely to be long felt. He was sprung from a medical family, his grandfather having been a medical practitioner in Ilkley in Yorkshire, while his father, the late Mr. John Syer Bristowe, M.R.C.S., L.S.A., practised for many years in Camberwell. His mother was one of the Chesshyres of Cheshire, a very ancient family, as indeed was also that of Bristowe. Dr. Bristowe was born at Camberwell in 1827, and after spending a few years at preparatory schools was educated at King's College. After leaving school he remained a year assisting his father at home. In the year 1846 he entered at St. Thomas's Hospital. At that date he had no greater ambition than to succeed to his father's practice, but in a fortunate moment he entered the London University, and his success at the matriculation examination, where, though he just missed the first place, he was specially sent for and complimented by the examiners, was his first encouragement to aim at a higher career. Once inspired with the desire to excel, the energy of his character and the power of his intellect finally asserted themselves. He took most of the prizes that were to be obtained at St. Thomas's Hospital, and in the year 1848 he was awarded the Treasurer's gold medal. He also obtained the Apothecaries' Society's gold medal in botany. At the intermediate examination in medicine at the London University in 1848 he took the exhibition and medal in materia medica. In 1849 he qualified as M.R.C.S. and L.S.A., and in the same year was appointed house surgeon to St. Thomas's Hospital. In 1850 he took his M.B. and obtained the medal and scholarship in surgery and the medal in physiology, and in the same year was appointed curator of the Museum of St. Thomas's Hospital. About the same time he became pathologist to the hospital and performed the duties of that office for ten years. In the same year he was appointed to assist the late Mr. Grainger in the lecture theatre. At this time his sympathies lay rather with surgery than with medicine; however, in the year 1852 he took his M.D. degree, and in 1854 was elected assistant physician to his hospital. In 1859 he became lecturer on botany, and in 1860 was appointed full physician and lecturer on materia medica. In 1865 he was appointed joint lecturer on general anatomy and physiology, and in 1870, on the retirement and at the request of Sir J. Simon, he was appointed lecturer on pathology. In 1876 he became lecturer on medicine, a post which he held until his retirement in 1892. On the death of Dr. Peacock he became senior physician. In 1856 he was appointed medical officer of health to Camberwell, and he held that office till his death. At the end of 1856 he married Miriam Isabelle, eldest surviving daughter of Mr. Joseph P. Stearns, of Dulwich, and afterwards of Cranbrook Park, Essex.

When the Commercial Union Assurance Company commenced a life department in 1862 he was appointed medical officer. This post he also retained until his death. He was also physician to Westminster School for over thirty years, and when the question of the removal of that school into the country was raised he used his influence strongly to prevent it. At the Royal College of Physicians of London he had a distinguished career. He was elected a Fellow in 1858. He was examiner in medicine in 1869 and 1870. In 1872 he was appointed Croonian lecturer, and chose for his subject "Disease and its Medical Treatment." In 1879 he was appointed Lumleian lecturer, the subject then being "The Pathological Relations of Voice and Speech." He was Censor in 1876, 1886, 1887, and 1888, and Senior Censor in 1889. As an examiner he held appointments at the Royal College of Surgeons of England, London University, Oxford University, and the War Office, which last he held at the time of his death. In 1881 he was elected a Fellow of the Royal Society, and was given the honorary LL.D. at the Tercentenary Festival of Edinburgh University, at which he was appointed to represent St. Thomas's Hospital. He was one of the early members of the Pathological Society, and he never ceased to be grateful to the late Dr. Peacock for having induced him to join. He was President in 1885, and his earliest writings are in the third volume of its Transactions. He was President of the Medical Society and Lettsomian lecturer in 1893; President of the Metropolitan Counties Branch of the British Medical Association in 1887; and President of the Neurological Society in 1891. He was also President of the Society of Medical Officers of Health. He was Vice-President of the Sanitary Protection Association; Corresponding Member of the Edinburgh Medico-Chirurgical Society; and Honorary Member of the Ophthalmological Society, of the West Kent Medico-Chirurgical and the Sydenham District Societies. When the West-end Hospital for Diseases of the Nervous System was reorganised he was appointed consulting physician, and he was recently appointed consulting physician to the Victoria Hospital for Children. On the resignation of the late Sir Andrew Clark he accepted the presidency of the Hospitals Association in spite of strong opposition against that body displayed by many of his medical friends. He also interested himself greatly in and was on the council of the Royal National Pension Fund for Nurses. In his earlier days he did a considerable amount of sanitary work for the Public Health Department of the Privy Council. He reported on phosphorus poisoning in the manufacture of matches in 1862, on infection by rags and paper works in 1865, and, in conjunction with Professor Burdon Sanderson, on the cattle plague. In 1863 he reported with Mr. Holmes on the sanitary condition of English hospitals. All of these reports are buried in Bluebooks.

JOHN SYER BRISTOWE, M.D., F.R.C.P LOND., &C.

As a physician probably his reputation stood highest in the department of diseases of the nervous system, and by many of the public as well as of the profession he was regarded as a specialist. His wards always contained a large number of most interesting cerebral and spinal cases. Many of these were specially sent to him, some from long distances. The classes of cases which specially interested him were perhaps cerebral tumours, cerebral syphilis, thrombosis of the sinuses, hysteria, general paralysis, locomotor ataxy, disseminated sclerosis, and paralysis agitans. He threw much light on the diagnosis of tumours of the corpus callosum, and gave

Digitized by Google

a very valuable description of the symptoms of that affection. He successfully diagnosed many very obscure cases of cerebral tumour, often localising them very exactly. The cases of "Marion" and "Jimmy," well known to his old pupils, were the exceptions which proved the rule. In the case of "Jimmy," who, after being long an inmate of St. Thomas's Hospital, was taken in at Guy's Hospital and eventually died there, the diagnosis of cerebral tumour made at both hospitals was found to be erroneous, the disease proving to be chronic hydrocephalus. In the case of "Marion," who was an inmate of St. Thomas's Hospital for nearly three years, the original diagnosis of cerebral tumour was given up some time before she died and that of structural disease substituted. No lesion, however, was discovered at the necropsy. To his early recognition of the syphilitic nature of a cerebral affection many a patient owed his life or escape from incurable paralysis. The subject of cerebral syphilis he ably discussed in his Lettsomian Lectures before the Medical Society of London. His work in connexion with the symptoms and diagnosis of thrombosis of the cerebral veins and sinuses also deserves special mention. Of immense value to his pupils was his teaching on the subject of hysteria. From time to time he had most extraordinary examples of this disease under his care. He sometimes, although rarely, took a case of functional disease to be organic, but it was very exceptional, if it ever occurred, for him to diagnose a case as functional which proved to be otherwise. He would tell with much delight of cases where his diagnosis of organic disease had been falsified. He was constantly illustrating and impressing on his pupils the difficulties of diagnosing general paralysis of the insane in its early stages, and often demonstrated the symptoms of the disease both in early and in well-marked cases. Although neurology had a great fascination for him he took an equal interest in diseases of the abdomen and chest. He always examined his cases with very great care. He was an excellent auscultator, and the conclusions he arrived at from physical examination were always very accurate. He had a very large experience of abdominal cases, and his opinion in such was highly prized. He was always ready to go down to the hospital at any hour of the night to see a case of urgency. The cases he was most frequently called to in this way were those of acute intestinal obstruction. In these, wherever the conditions were favourable, he called into requisition the services of the surgeon at the earliest opportunity.

It has sometimes been said of Dr. Bristowe that he belittled treatment and that he did not believe in drugs. Such was really far from being the case. He was ever ready to give such drugs as had a proved value. He would quickly give iodide of potassium in syphilis, salicylate of soda in rheumatism, arsenic in pernicious anæmia, iron in chlorosis, and opium, digitalis, bromide of potassium, &c., where he thought they would be beneficial. He was, on the other hand, strongly opposed to irrational therapeutics and always expected to be given a sufficient reason as to why a certain drug had been prescribed by his house physician. Where there was no special indication for any particular drug his favourite prescription was compound infusion of gentian.

In 1887 his time as physician to St. Thomas's Hospital came to an end; but by the unanimous wish of his colleagues he was requested by the governors to retain his position for another five years. In 1892 he retired and was elected consulting physician and governor. On the occasion of his retirement his old pupils and colleagues subscribed to a testimonial for him, a portion of which was expended on a portrait of himself which was painted by one of his daughters and presented to St. Thomas's Hospital. The greater part of the money collected was, however, at his own request devoted to founding an annual medal as a prize for pathology.

Dr. Bristowe's contributions to medical literature were numerous and valuable. His style of writing was lucid and simple, and he was one of the greatest masters of the English language which the medical profession has possessed. His best-known work was "The Theory and Practice of Medicine," which was first published in the year 1876 and has passed through seven editions. This book has always been one of the leading text-books on medicine and has made his name familiar to the medical profession both in England and abroad. One of the most valuable portions of this work is the chapter on insanity, which was the result of original investigations carried out with the utmost care and patience. In 1888 he published a volume on "Diseases of the Nervous System," which was a compilation of cases. At that time it was his intention to publish similar volumes on diseases of the rest of the body, a work which failing health unfortunately prevented him from accomplishing. To show how varied was the bent of his mind we may refer especially to his presidential address at the Neurological Society, when the subject he chose was "The Relation of Mind to Brain," and his pamphlet on the nature of the Welsh "Ll," in which he showed that it was really an aspirated "l." He also gave much time and attention to the teaching of the dumb to speak and to the question of the formation of the various letters. On this matter he was held as an authority. His varied contributions to the medical journals and societies are too numerous to mention here.

As a teacher Dr. Bristowe was unsurpassed, and so much was his clinical work appreciated that many distinguished physicians of the day were wont to accompany him round his wards; indeed, it may almost be said that as a teacher he displayed his greatest powers, and only those who were privileged to learn from him can properly appreciate the great loss that medicine has sustained. He did not attempt to teach in the wards what might equally well be learnt in the school. He never adopted the plan of sitting down to one particular case and making it a text on which to discourse about the etiology, symptoms, physical signs, diagnosis, &c. of the disease concerned and of perhaps half a dozen other diseases with which it might be confounded. His method was a very different one. He seldom dwelt very long on one individual case, for in the course of his round of two or three hours he made a point of seeing every patient and saying something about each. He would ask for the report of the clinical clerk and house physician, or he would perhaps himself give a short *résumé* of the case. He would then carefully examine the patient and ask some of the students to do so also, attracting their attention to points of difficulty or of special interest. He would ask for opinions and then give his own with his reasons for it. He would often relate *à propos* of a case others from his rich experience which would help to throw light on it. This relation of cases formed a most valuable part of his teaching. He had a wonderful memory, and could recall small details about a case which he had seen perhaps years previously.

It was largely owing to a letter addressed by him to Lord Granville, then Chancellor of the London University, that the question of increasing the facilities for the obtaining of degrees by London medical students is in its present position. During the Marquis of Salisbury's Administration in 1886–92 he was placed on the Royal Commission to inquire into Vaccination, and as long as health permitted he worked hard on its behalf. He devoted most of his time to his professional work, but was no mean artist. In his earlier days he studied painting, and had some thought of devoting his life to art. In his student days he was in the habit of drawing portraits of his teachers, fellow students, and others, a practice he continued through life, and he has been said to have frightened candidates at examinations by this habit. At the age of seventeen he published a volume of poems; since then he has written many others, and during the last few years has published a further volume.

Of Dr. Bristowe's mental and moral qualities little remains to be said. To the outside world he was a quiet and courteous gentleman. To those who had the privilege of his intimate acquaintance he was an attached and faithful friend; and no man was more capable than Dr. Bristowe of inspiring love and admiration. It may be added that he had a considerable fund of humour and was an excellent host. His mind was essentially great. He was absolutely without crotchets and was incapable of petty jealousy or of any mean or paltry act. In his aims he was guided solely by considerations of duty, without regard to personal or selfish motives. His opinions were only formed after mature thought; but when once he had formed them nothing could induce him to depart from the course which he considered to be the right one, even though that course might be detrimental to his own interests. On several occasions during his career this characteristic manifested itself. One of these, which will probably recur to many of our readers, was in 1881, when he ventured in the face of general professional opposition to assert the propriety of not refusing to meet homœopaths in consultation.

His illness dated from the death in 1892 of his brother, Thomas Lynn Bristowe, late M.P. for Norwood, which

Digitized by Google

powerfully affected him. This was followed by an attack of influenza, which left trouble behind it, of which his premature death was the final result. Within a week of his end he went with his family to Monmouth in the hope of recruiting his strength. Though he appeared to arrive there in his usual health and in good spirits symptoms of cardiac failure manifested themselves after a few days. He passed away quietly in the presence of his wife and family.

For the following appreciative estimate of the life and work of Dr. Bristowe we are indebted to Dr. W. M. Ord, who was his life-long friend:—

"It is now forty-two years since, as a first year's student at St. Thomas's Hospital, I made the acquaintance of Dr. Bristowe. He was then Lecturer on Botany, and although only some twenty-seven years of age was clearly marked out for distinction. He had been first in his year during his student career, and had attained a very high position in the examinations for the degree of Doctor of Medicine in the University of London, taking more than one scholarship and several medals. His lectures on botany had a distinct attraction for an earnest student. They were delivered with ease and with a singular freedom from affectation, particularly the affectation of superior knowledge or authority. With a frankness characteristic of him through life he was wont to say that he really knew nothing about botany. This was far from true; for, as a result of hard reading and practical study with the microscope, he was much more than sufficiently versed in structural botany, to which he devoted the larger part of his course. It was natural to him to like this kind of investigation, and his logical mind enabled him to put before his class such things as the minute anatomy, the reproduction, and the morphology of the chief divisions of the vegetable kingdom in a terse, coherent, and suggestive form admirably calculated to stimulate the exploring faculty in his hearers. To classification he paid little more than formal attention. Out of class he was genial and affable, setting us, his pupils, perfectly at ease in his presence. Hence a botanical excursion with him as leader was a truly pleasant function, for we felt as we traversed lane, wood, and down with him that our teacher was, notwithstanding his high attainments, of our own flesh and blood. His studies in botany had not included much more than medicinal plants and the ordinary types of orders. When a plant was brought to him which he could not identify he said quite plainly that he did not know it. The avowal and the comic smile with which it came increased our respect for the true man that he was. We were, of course, conscious that he was not specially a botanist, but that he was filling the chair, according to the practice of the time, as a step in medical promotion. None the less, however, did we feel the value of what he taught us. Such early experience was soon after followed by his introduction to us in the wards, in the out-patient department, and in the post-mortem room. In common with the rest of the assistant physicians, he was allotted a few beds in the medical wards. In all these scenes of practical work we found him again the helpful teacher, full of *camaraderie* on the one hand, and, on the other, in knowledge and method a master, himself striving every day to advance medical knowledge. Those who followed him then and after will never forget his painstaking examination of patients, his minute and extensive record, and his pictorial description of symptoms. As he took the cases they came out clear for diagnosis or discussion of diagnosis, with acute note of everything that was irregular or novel. Further, a remarkable facility in drawing enabled him to illustrate on paper or the blackboard the probable conditions of viscera &c., just as the same facility, freely used, had helped to give life to his lectures. He certainly showed an abiding temptation to the artistic use of pen or pencil, mostly of the pen. When a clinical student he might frequently be seen sketching endless varieties of heads, of animals, and *grotesqueries*, generally in excellent style, on the well-suited calf in which the old ward-books were bound. When one of these covers was completely filled, the sketches were touched up and linked by lines and shading, the fantasies of his pen becoming objects of admiration and cupidity. Mr. Whitfield, then medical secretary, became possessed of several of them, his well-known collecting genius appreciating their value and treasuring them accordingly. I think that Bristowe kept one or two; the rest are probably scattered amongst the mementoes of his old fellow students—mementoes of the time and the man. This habit never left him. So long as he continued to attend meetings and committees at the hospital he continued to leave on the foolscap placed on the table drawings and caricatures to be garnered afterwards by appreciative hands. It is, of course, well known that he had early in life and at a later period published many poems of considerable merit, displaying the same imaginative faculty which, in addition to skill of hand, made the value of his sketches. It came to pass, as I knew him more, that two things greatly perplexed me. First, the accomplished artist wrote a hand which, though not ugly, was difficult to read on account chiefly of the blurring of the ends of words and the imperfect formation of many of the letters. He could write plainly enough when he gave his mind to it, but as his thoughts were placed upon paper they seemed to outstrip his pen, leaving a dash here and a wavy line there, only to be interpreted, if interpreted at all, by a reader who had carefully followed the train of argument or the course of statement in which they were intended to play their part. On this point he used to tell with great enjoyment a story against himself. In an examination at the University of London, when he came up for the vivâ-voce his examiner placed before him several words cut out of his papers and asked him to read them to him. In the absence of the context he was unable to supply the information. It was creditable to the patience of the examiner (the late Dr. Carpenter) that he did read the papers, and in the end awarded the scholarship in competition for which they were written to Bristowe. The second puzzle was that the man of imagination should be so strongly filled with a spirit of scepticism as to be a worthy follower of the Apostle after whom our hospital is named. In Bristowe's case imagination was tempered and more than controlled by an innate tendency to questioning, both in regard of facts and inferences. The question did not go so far even as 'Why?' but stopped first at 'Is it so?' leaving the 'Why' to be considered if the answer to the first question was satisfactory enough to allow him to proceed to the second. He could, fairly enough, take nothing for granted; he seemed, however, to go further and to take up a position almost hostile to any new thing, great or small. He would be as slow to accept the existence of a valvular murmur or a friction sound which had been noted by his assistants as to adopt a new theory of the meanings of the heart-sounds in health or disease. This slowness of conviction led him on to most valuable investigations. He would often, in spite of the already accepted opinions regarding them, follow out for himself the intricacies of many obscure symptoms and diseases, sometimes confirming, sometimes dissenting from, the earlier decisions, rarely without adding materially to our knowledge. He was thus always determined to make sure of his evidence, always determined to see, if possible, the truth, independently of all the weight of existing authority. None but those who have carefully followed his work know the great value which this stern spirit of true investigation has attached to it. It appears to me that the whole school of St. Thomas's has been deeply impressed and most wholesomely disciplined by the word and example of Bristowe, himself doubtless influenced, as no doubt others have been, by the severe rules of conscience inculcated by George Rainey. Onward, as time allowed him to verify things that had been often more than doubtful to him, he was able to form conclusions. The scepticism, which had almost amounted to prejudice, tended then to be in many instances replaced by a conviction. Once satisfied, he would support the new or received idea and would do battle for it as strongly as he had before doubted it.

"'There lives more faith in honest doubt,
Believe me, than in half the creeds.'

This is assuredly true of the man whose loss we have at heart. His mental attitude in controversial matters was well seen in respect of his political opinions. For a great part of his life he was a Liberal in politics; but when the Home Rule question filled the field he felt impelled to his wonted process of examination, with the result that he became first a Liberal Unionist, and afterwards something very like a Tory. In one point his scepticism has produced an impression which is far from just or true; I mean in regard of his way of dealing with therapeutics. He is generally said to have given too little attention to the subject of therapeutics, alike in his great work on Medicine and in his hospital teaching. In my belief he could not preach

Digitized by Google

many uses of drugs and many accessory treatments because he had not sufficiently proved them. He seems to have felt like David in face of the armour provided for his use. Yet he could use the sling and the stone effectively, and many a time have I seen him trying the armour in hope of availing himself of it when he understood its application. I remember very well witnessing his careful trials of injections of salt water and dealbuminised serum into the veins of cholera patients in 1854. And I know that he urged strongly the establishment of a complete installation of baths of all kinds in the new hospital on the Embankment, in view of a thorough estimation of their remedial applications. Those who knew him know well that it was only the same caution which forbade him to give an absolute diagnosis in a case of doubtful diagnosis which forbade him also to teach decisively any method of treatment about which he was not absolutely certain. For all of us diagnosis must precede treatment. I say without hesitation that diagnosis was so regarded by him, and that he neither despised nor failed to make active use of therapeutics wherever his reasoning allowed. The world may be sure that whatever he said or left unsaid was determined by the use of a strict judicial estimation of the value of the information supplied to him by his extraordinary industry in reading and in research. Those only who have toiled as he toiled can fairly judge him in respect of the matters which have been noted. They are indeed few. In what I have so far written I have put down my recollections of Bristowe as I first saw him, and I have tried to trace the development of the qualities which were then apparent in him.

"As time passed we became colleagues, and I was then admitted to his more intimate friendship and to his home. While I learned more, now, of his vast professional knowledge, I came to learn more of his true, generous quality of heart in dealing with his fellow men, even where he was determinedly opposed to their opinions. I saw the kindly fairness underlying that appearance of rigidity, scarce short of obstinacy, which seemed to make him a hard judge of both theories and actions, and many a time have I felt the kindness and the thrust, only with increase of the trust and the affection which he inspired. His innate fairness, indeed, with his kindliness, led him some years ago to give an address at Ryde of so lofty a character as to expose him to much harsh comment on the part of the people who could not reach to his standpoint. His inner life was essentially domestic. The hours devoted to work were succeeded by a happy life in the family, full of all kinds of wholesome activity. In his recreations he was alike simple. It was his delight to go with his wife and children to places where nature provided the best of society. In such places he would revel, taking long walks with his family and friends, letting the imaginative part of his being find food and response in the hills, by the sea, and on many a country side. Then, the cares of life, the trammels of the daily duty, and the requirements of the publisher forgotten, he would read aloud the glorious page before him, always with some fresh intonation. If I may dare to add a word I should like to say with deep respect how much he was helped by the companionship of his bright, clever, and affectionate wife who is now left to bear the great sorrow of her life. Others, doubtless, will state in detail the achievements of Bristowe's career. They are, indeed, well-known. Whatever they may cover in recital, they cannot cover all that he has done for medicine and for medical men. They can never reveal the influence which he has exerted on fair investigation or the widespread influence of his teaching of the higher class of students during the last four decades. He lived, so to speak, in teaching, in imparting to chosen young men of the higher aptitude the results of his long years of observation and experience. His words have truly, in one way and another, gone out to the ends of the earth. A true, generous, and affectionate friend, he has left a void which can never be filled for those who knew him closely. He was *justus et tenax propositi*, and was ever above the *civium ardor prava jubentium*."

The following is from the pen of a Fellow of the Royal College of Physicians of London who was much associated with Dr. Bristowe and enjoyed the benefit of his friendship:—

"The loss of Dr. Bristowe is a matter for more than ordinary regret, for he was an exceptional man whose character and whose turn of mind tended to exalt the profession to which he belonged. There probably never was a man who practised medicine with less of the commercial bias. He had in him much of the philosopher, nothing of the advertiser; he combined a keen logical faculty with absolute truthfulness, which he brought to bear not only upon his relations to others, but in regard to his own convictions. He was by nature and habit a sceptic, and carried his scepticism into therapeutics, not, perhaps, beyond the wisdom of a philosopher who would not venture further than he was sure of, but too far for the worldly-wise who may often prescribe with more assurance of satisfying the minds of their patients than of benefiting their bodies. He was great as a pathologist, great as an observer of disease in its natural course, and great as a clinical teacher. Critical and uncompromising, he was rather a great professor than a popular practitioner. He followed his line of thought whithersoever it led and never shrank from conclusions which his premisses indicated. Conscientious to the total disregard of his interests, he was 'too fond of the right to pursue the expedient.' It is possible that his consciousness of rectitude of purpose and of logical consistency may have sometimes made him appear pertinacious and even captious to men whose minds were of more slack fibre and whose habitual practice was compromise. In all his personal relations he was kindly, benevolent, and genial. His many friends mourn the loss of one to whom they were closely attached, while the whole profession is made the poorer by the death of an able and honest physician whose whole life was a protest against the authorised quackery of the ignorant, the pretentious, and the insincere."

Medical News.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGES OF PHYSICIANS AND SURGEONS.—The following gentlemen passed the First Examination of the Board in the subjects indicated, under the "five years" regulations, viz.:—

Part I.—Chemistry and Physics:—

Adams, Ernest Beadon Dixon, St. Bartholomew's Hospital.
Adams, Henry Cyril, St. Bartholomew's Hospital.
Alderson, Percy Francis, Middlesex Hospital.
Ashley, Herbert Ernest, St. Bartholomew's Hospital.
Asten, Walter, Mason College, Birmingham.
Atkinson, George James Smith, St. Paul's School, West Kensington.
Austin, Elfred Chalmers, St. Mary's Hospital.
Aylen, Ernest Vaughan, London Hospital.
Baker, Dodington George Richard Sherston, University College, London.
Baker, William Lincoln, St. Mary's Hospital.
Barnes, George, St. Mary's Hospital.
Bartlett, Ernest John Reeve, King's College, London.
Bastian, William, University College, London.
Batchelar, Arthur, University College, London.
Baxter, Charles Thomas, Middlesex Hospital.
Beale-Browne, Thomas Richard, Guy's Hospital.
Beare, Joseph, Firth College, Sheffield.
Beley, Stanley, St. Thomas's Hospital.
Bell, John Cunningham, University College, London.
Bigg, Reginald, St. Bartholomew's Hospital.
Bignold, Henry Howe, Guy's Hospital
Blake, Percy Ryall, London Hospital.
Bostock, Arthur Hastings, St. Bartholomew's Hospital.
Bradley, Richard Walter, St. Mary's Hospital.
Brangwin, Charles Harold, Guy's Hospital.
Braund, Henry, Guy's Hospital.
Brockwell, John Brocas Chambers, Guy's Hospital.
Brown, Thomas Warren, St. Bartholomew's Hospital.
Browne, Thomas Walker Stanley, Guy's Hospital.
Burd, Reginald Shirley, Mason College, Birmingham.
Chalk, Charles Launder, St. Bartholomew's Hospital.
Challans, Frank, London Hospital.
Chaplin, Henry Ayrton, St. George's Hospital.
Churchill, John Aylward, St. George's Hospital.
Coleridge, Alfred, University College, Bristol.
Compton, Alwyne Theodore, St. Bartholomew's Hospital.
Compton, Maurice Winzar, St. Thomas's Hospital.
Cooke, Reginald Torriano, St. Bartholomew's Hospital.
Cory, Harold Myrle, Mason College, Birmingham.
Crompton, Richard Henry, University College, Liverpool.
Cunningham, John Francis, St. Thomas's Hospital.
Davies, Arthur Gerald Capel, Guy's Hospital.
Denny, Herbert Reginald Harry, Guy's Hospital.
Dismorr, Henry Bertram, Guy's Hospital.
Douglas, William Claughton, St. Bartholomew's Hospital.
Dudgeon, Leonard Stanley, St. Thomas's Hospital.
Edmonds, Charles John Ernest, St. Thomas's Hospital.
Edwards, Charles, Guy's Hospital.
Elliott, James Warner, St. Mary's Hospital.
Evans, Sydney James, Guy's Hospital.
Farquharson, Charles Henry, St. Mary's Hospital.

Fawssett, Basil, St. Thomas's Hospital.
Felton, Edgar Hall, Guy's Hospital.
Foulds, Francis Henry, St. Mungo's College, Glasgow.
French, Frank Austin, St. Mary's Hospital.
Garne, Sydney William, Charing-cross Hospital.
Goode, George Ernest, London Hospital.
Griffith, John Richard, London Hospital.
Gubbins, John Gaspard, St. Thomas's Hospital.
Harbinson, Robert James, St. Mungo's College, Glasgow.
Hart, John Hamilton, St. Thomas's Hospital.
Harvey, Joseph Frederick, Mason College, Birmingham.
Hawes, Ivon Henry Skipworth, St. George's Hospital.
Hawthorn, Henry William John, Mason College, Birmingham.
Heanley, Charles Montague, St. George's Hospital.
Hepper, Evelyn Charles, St. Bartholomew's Hospital.
Heseltine, Verner George, St. Bartholomew's Hospital.
Hicks, Charles Edward, Guy's Hospital.
Higgens, Hugh Arthur, Guy's Hospital.
Higson, Thomas, Owens College, Manchester.
Holland, Edward Torriano, St. Paul's School, West Kensington.
Hollick, Hubert Harry, Mason College, Birmingham.
Holmes, Willmot, St. Mary's Hospital.
Hubert, Edgar Hamilton, St. George's Hospital.
Humby, Harry Robinson, St. Bartholomew's Hospital.
Hutton, Ernest Wilberforce, St. Thomas's Hospital.
James, William Warwick, Middlesex Hospital.
Jupp, Ralph Tennyson, Mason College, Birmingham.
Last, Cecil Edward, St. George's Hospital.
Leech, Frederick Samuel, University College, London.
McClintock, John. King's College, London.
McQueen, Robert Martin, University College, Bristol.
Manning, Ernest John, St. Mary's Hospital.
Marrett, Henry Norman, St. Bartholomew's Hospital.
Mason, Herbert Alfred, Firth College, Sheffield.
Miles, William Percival, St. Bartholomew's Hospital.
Miller, John, Owens College, Manchester.
Morris, Herbert Edward, Guy's Hospital.
Navarra, Norman, Middlesex Hospital.
Newton, Arthur Charles Duncan, Bedford Grammar School.
Noakes, Fred., Charing-cross Hospital.
Nicholls, Percival Thomas, Middlesex Hospital.
Oates, James Christopher, Mason College, Birmingham.
Parker, Christian, London Hospital.
Parsons, Ernest Alsager, Mason College, Birmingham.
Paul, John Frederick, St George's Hospital.
Perkins, Philip Meyler, St. Bartholomew's Hospital.
Pern, Sydney, St. Thomas's Hospital.
Pinches, Henry Irving, St. Paul's School, West Kensington.
Pinches, Horace George, St. Thomas's Hospital.
Pinker, Henry George, St. Bartholomew's Hospital.
Pollock, Aubrey Keating Halliday, St Bartholomew's Hospital.
Pretty, Harold Cooper, University College, London.
Pugh, Arthur Bailey, St. Bartholomew's Hospital.
Randolph, William Henry, St. Bartholomew's Hospital.
Robertson, James Fenwick, St. Bartholomew's Hospital.
Rogers, Frederick Colin, St. Mary's Hospital.
Rodil, Baltasar, Guy's Hospital.
Scorah, Ernest John, Firth College, Sheffield.
Scott, Edward Fletcher, Guy's Hospital.
Shorland, George, Guy's Hospital.
Simpson, George Herbert, St. Mungo's College, Glasgow.
Simpson, John Edgar, University College, London, and King's College, London.
Smith, Francis Maylett, St. Paul's School, West Kensington.
Smith, Sydney Joseph, Charing-cross Hospital.
Smith, Thomas William, Charing-cross Hospital.
Softly, Alfred Ernest, St. Thomas's Hospital.
Speirs, George Benjamin Armes, St. Mary's Hospital.
Stanley, Edmund Hamilton Blake, University College, London.
Steen, Wilfred Alexander, London Hospital.
Symons, Vivian Hood, Mason College, Birmingham.
Takaki, Yoshihiro, St. Thomas's Hospital.
Talbot, Ashley West, Guy's Hospital.
Tayler, Henry Christopher, St. Mary's Hospital.
Thompson, Joseph Bernard, University College, London.
Thorne, Richard Thorne, St. Bartholomew's Hospital.
Turle, James Evan, University College, London.
Twort, Frederick William, St. Thomas's Hospital.
Tytheridge, Ainslie Burton, St. Paul's School, West Kensington.
Vickers, Thomas Hedley, St. Mary's Hospital.
Visger, Charles, University College, London.
Wagstaff, Charles Bertrand, Charing-cross Hospital.
Walker, Robert, St. Bartholomew's Hospital.
Ward, Oswald Erasmus, Mason College, Birmingham.
Waters, Alfred Charles Stanley, University of Cambridge.
Welch, Frederick Day, London Hospital.
Westlake, Bernard Beaumont, Guy's Hospital.
Whitehouse, Mervyn Turberville, Mason College, Birmingham.
Wilson, Richard Eldred, London Hospital.
Woodcock, Henry Cnadwick, St. Mary's Hospital.
Yule, Bransby, University College, London.

Part II.—Practical Pharmacy:—

Acland, Hugh Thomas Dyke, St. Thomas's Hospital.
Alderson, Francis Bellairs, Firth College, Sheffield.
Allen, Thomas Percival, St. Bartholomew's Hospital.
Anley, Frederick Eustace, Charing-cross Hospital.
Ashley, Herbert Ernest, St. Bartholomew's Hospital.
Barwell, Francis Reinagle, University College, London.
Bateman, Herbert Raymond, St. Thomas's Hospital.
Beaumont, Noel Charles, St. Bartholomew's Hospital.
Bell, Robert John, Charing-cross Hospital.
Bevan, Arthur, St Thomas's Hospital.
Bingham, Frank Miller, St. Thomas's Hospital.
Bradley, Alwyn Hewett, Mason College, Birmingham.
Braund, Henry, Guy's Hospital.
Bullen, Edward Harry, St. Mary's Hospital.
Burrows, Harold, St. Bartholomew's Hospital.
Calvert, Herbert, St. Thomas's Hospital.
Chapman, Donald Poyntz, Charing-cross Hospital.
Chetwood, Thomas, London Hospital.
Churchill, John Aylward, St. George's Hospital.
Churton, John Gaitzkill, University College, Liverpool.
Collyns, John Moore, St. Bartholomew's Hospital.
Compton, Maurice Winzar, St. Thomas's Hospital.
Corbett, Sidney d'Alton, St. George's Hospital.
Cornish, Charles Vivian, St. Bartholomew's Hospital.
Cory, Harold Myrie, Mason College, Birmingham.
Danks, Walter Seymour, St. Bartholomew's Hospital.
Davey, John Bernard, Middlesex Hospital.
Davies, Daniel, St. Bartholomew's Hospital.
Davies, David Leighton, University College, London.
Davies, Enoch Howell, University College, Cardiff.
Dawson, Edwin Norman de Vere, St. Thomas's Hospital.
Denniston, William Edward, St. Thomas's Hospital.
Dixon, Godfrey Brookes, Charing-cross Hospital.
Doubble, Meredith Sedgwick, Charing-cross Hospital.
Douglas, William Claughton, St. Bartholomew's Hospital.
Drake-Brockman, Henry George, St. George's Hospital.
Eastment, Gerald Meade, Middlesex Hospital.
Ellery, Richard Frank, St. Bartholomew's Hospital.
Elwes, Frederick Fenn, Middlesex Hospital.
Evans, William, Otago University and London Hospital.
Faulkener, Erasmus Oakes, St. Mary's Hospital.
Fawssett, Wilfred, St. Thomas's Hospital.
Frost, Cecil Scarlett, St. Bartholomew's Hospital.
Gaff, James, St. Thomas's Hospital.
Gandy, Thomas Hall, St. Bartholomew's Hospital.
Gilbert, Walter Raleigh, St. Thomas's Hospital.
Hagon, Albert, University College, Cardiff.
Hamilton, William Gavin, St. Bartholomew's Hospital.
Hancock, William Edwin Harry, University College, Bristol.
Harris, Herbert Stocker, St. Thomas's Hospital.
Harris, William Trengweath, St. Thomas's Hospital.
Hartley, John Dawson, St. Bartholomew's Hospital.
Harvey, Joseph Frederick, Mason College, Birmingham.
Hayes, Arthur Herbert, St. Bartholomew's Hospital.
Heath, Philip Maynard, University College, London.
Higson, Thomas, Owens College, Manchester.
Hodgsons Robert Edward, St. Mary's Hospital.
Hope, Walter Bayard, Guy's Hospital.
Hudson, Edmund, St. Thomas's Hospital.
Humphreys, Jack Edmund, Charing-cross Hospital.
Illius, Henry Warwick, St. Bartholomew's Hospital.
Illius, John Warwick, St. Bartholomew's Hospital.
Inman, William Sam, Firth College, Sheffield.
Jameson, Archibald Douglas, St. Thomas's Hospital.
Jones, Arthur Webb, St. Thomas's Hospital.
Jones, William Forsyth, Charing-cross Hospital.
Judson, Joseph Edward, Owens College, Manchester.
Jupp, Ralph Tennyson, Mason College, Birmingham.
Lamborn, William Alfred, Middlesex Hospital.
Leech, Frederick Samuel, University College, London.
Lees, Charlie, Charing-cross Hospital.
Lilley, Ernest Lewis, Charing-cross Hospital.
Lobb, Hubert Peché, St. Bartholomew's Hospital.
Law, George Harvey, St. Bartholomew's Hospital.
McLachlan, Arthur Ronald, Guy's Hospital.
McLeod, James Alexander, London Hospital.
Martin, Malcolm Murcott, St. Bartholomew's Hospital.
Mayne, William Boxer, University College, London.
Merry, Edward, London Hospital.
Mitchell, Talbot Carter, Yorkshire College, Leeds.
Morley, Arthur Solomon, St. George's Hospital.
Navarra, Norman, Middlesex Hospital.
New, John Sherwood, University College, London.
Nunn, John Wilfred, St. Bartholomew's Hospital.
Nutt, Harold Rothery, St. Mary's Hospital.
O'Hea, John, St. Bartholomew's Hospital.
Olivey, John Michael Abraham, St. Thomas's Hospital.
Parsons, Ernest Alsager, Mason College, Birmingham.
Passmore, William Henry, Charing-cross Hospital.
Peck, William Edward, University College, London.
Perrin, Thomas, St. Thomas's Hospital.
Pitts, Arthur Gentry, Charing-cross Hospital.
Pritchett, George William Morris, University College, London.
Quinby, Frank Gray, University College, Liverpool.
Reid, Archibald Douglas, King's College, London.
Rodil, Juan José, Guy's Hospital.
Russell-Risien, Ernest, St. Bartholomew's Hospital.
Sanders, James Herbert, London Hospital.
Scorah, Ernest John, Firth College, Sheffield.
Scott, Henry Martin, Charing-cross Hospital.
Scott, Sydney Richard, St. Bartholomew's Hospital.
Scrase, James John Sheat, St. Bartholomew's Hospital.
Smith, William Christian Baumgarten, St. Bartholomew's Hospital.
Softly, Alfred Ernest St. Thomas's Hospital.
Sprague, Francis Henry, St. Mary's Hospital.
Stevens, Stanley, St. Bartholomew's Hospital.
Stone, Gerald William, St. Bartholomew's Hospital.
Stratford, Howard Blenheim Martin, Oxford University.
Takaki, Yoshihiro, St. Thomas's Hospital.
Thomas, Harold Sebert, St Bartholomew's Hospital.
Trumper, William Arthur, St. Mary's Hospital.
Turner, Walter Edward, St. Mary's Hospital.
Vaughan, Arthur Llewellyn, St. Bartholomew's Hospital.
Walker, Lewis Augustus, St. Bartholomew's Hospital.
Walters, Charles Ferrier, University College, Bristol.
Waters, James, Middlesex Hospital.
Wells, Albert John Walton, St. Bartholomew's Hospital.
Williams, Gwilym Went Steuart, St. Bartholomew's Hospital.
Wirgman, Charles Wynn, University College, London.
Woodforde, Robert Edmund Heighes, St. Bartholomew's Hospital.
Wood-Hill, Henry Gilbert, St Bartholomew's Hospital.
Yule, Bransby, University College, London.

Stokes, Percy Southwell, Firth College, Sheffield.
Thwaites, Cyril Evered, St. Mary's Hospital.
Thwaites, Harry, London Hospital.
Townroe, Eugene Dunbar, St. George's Hospital.
Turner, Charles Harold, St. Bartholomew's Hospital.
Waters, Alfred Charles Stanley, Cambridge University.
White, Charles Vaughan, St. Thomas's Hospital.
Whitehead, Arthur Ernest, Firth College, Sheffield.
York, Thomas, Westminster Hospital.

Part IV.—Elementary Anatomy:—

Austen, Cecil Cress, Westminster Hospital.
Barnes, George, St. Mary's Hospital.
Brangwin, Charles Harold, Guy's Hospital.
Brown, Thomas Warren, St. Bartholomew's Hospital.
Capper, Harold Selwyn, University College, London.
Carlyon, Arthur Farrington, Middlesex Hospital.
Clayton, John Cecil, University College, Bristol.
Crawley, Herbert Edward, Oxford University.
Cross, Gerald Coneybeare, Middlesex Hospital.
Daly, Frederick James Purcell, London Hospital.
Davies, David Morgan, St. Mungo's College, Glasgow.
Douglas, William Claughton, St. Bartholomew's Hospital.
Durance, William Arthur, Westminster Hospital.
Edwards, Charles, Guy's Hospital.
Esser, Samuel Jonathan David, London Hospital.
Etheridge, Charles Edward, Middlesex Hospital.
Evans, William, Otago University and London Hospital.
Facey, Reginald Ambrose, St. Mary's Hospital.
Flint, Harold Edwards, St. Bartholomew's Hospital.
Forbes, Cyril Donald Edward, St. George's Hospital.
Foulds, Francis Henry, St. Mungo's College, Glasgow.
Gould, Reginald, London Hospital.
Gomez, Francisco José, King's College, London.
Green, Sydney Balch, St. Bartholomew's Hospital.
Halliday, John Rutherford, London Hospital.
Harris, John, University of Sydney, New South Wales.
Harris, Thomas Arthur Ball, Firth College, Sheffield.
Hawkes, Alfred Ernest Underwood, University College, Liverpool.
Hayes, Arthur Herbert, St. Bartholomew's Hospital.
Hemstead, Henry, University College, Bristol.
Hobbs, Albert Remington, St. Mary's Hospital.
Holmes, Wilmot, St. Mary's Hospital.
Hudson, Edmund, St. Thomas's Hospital.
Jones, Frederick John Felix, Guy's Hospital.
Judson, Joseph Edward, Owens College, Manchester.
Kerfoot, Stanley James, London Hospital.
Lakeman, Jasper, London Hospital.
Lawson, James Ward, Charing-cross Hospital.
Leclézio, George Joseph Alexis, St. Bartholomew's Hospital.
Leech, Frederick Samuel, University College, London.
Mansell, Thomas, St. Thomas's Hospital.
Martin, John Lemon, St. Mary's Hospital.
Page, Shirley, Mason College, Birmingham.
Palmer, William Grimes, Guy's Hospital.
Panckridge, William Panckridge, Middlesex Hospital.
Pick, Lawrence, St. George's Hospital.
Pinker, Henry George, St. Bartholomew's Hospital.
Quinby, Frank Gray, University College, Liverpool.
Raven, Eustace, St. Thomas's Hospital.
Reardon, Arthur Francis, St. Thomas's Hospital.
Roche, Ivan Joseph, Charing-cross Hospital.
Rockwood, David Pratt, University College, London.
Scott, Claude Sigismund, St. Bartholomew's Hospital.
Shorland George, Guy's Hospital.
Soderberg, John Emil, Westminster Hospital.
Stedman, Percy Taylor Humphry, University College, London.
Sykes, Walter, Owens College, Manchester.
Thompson, Cecil Charles Brandon, St. Bartholomew's Hospital.
Thwaites, Cyril Evered, St. Mary's Hospital.
Thwaites, Harry, London Hospital.
Walker, Robert, St. Bartholomew's Hospital.
Watson, William Bertram, St. Mary's Hospital.
Weston, Herbert Ernest, St. George's Hospital.
Woodforde, Robert Edmund Heighes, St. Bartholomew's Hospital.

SOCIETY OF APOTHECARIES OF LONDON.—The following candidates passed in—

Surgery.—A. F. Blake, London Hospital; G. W. Brown, St. Thomas's Hospital; J. A. Clough, Leeds; R. G. Jones, London Hospital; W. J. Lubeck, Madras; A. R. McCullagh, Charing-cross Hospital; and H. S. Maw, Bristol and St. Bartholomew's Hospital.

Medicine, Forensic Medicine, and Midwifery.—F. A. Blatchford, St. Mary's Hospital; J. A. Clough, Leeds; A. D. Parr Dudley, University College; R. E. T. Ingram, Guy's Hospital; H. S. Maw, Bristol and St. Bartholomew's Hospital; U. W. N. Miles, King's College; D. Pettigrew, Glasgow and Sheffield; and S. J. Wakeham, Charing-cross Hospital.

Medicine and Forensic Medicine.—J. G. Owen, Charing-cross Hospital; A. H. Wade, St. Bartholomew's Hospital; and R. P. H. Whitmarsh, St. Thomas's Hospital.

Medicine.—G. Lowsley, St. Bartholomew's Hospital.

Forensic Medicine and Midwifery.—D. D. Stewart, Liverpool; and T. W. Wakem, Charing-cross Hospital.

Forensic Medicine.—R. G. Jones, London Hospital; S. E. H. Martin, Royal Free Hospital; and M. White, St. Thomas's Hospital.

Midwifery.—O. W. Gange, University College; D. C. Kemp, University College; and J. Watts, Manchester.

To Messrs. Blake, Blatchford, Brown, Clough, Dudley, Ingram, Jones, Lowsley, McCullagh, Maw, and White was granted the diplomas of the Society entitling them to practise Medicine, Surgery, and Midwifery.

MANY interesting papers will be read at the approaching nineteenth meeting of the American Dermatological Association to be held at Montreal on Sept. 17th, 18th, and 19th. The proceedings will commence with an address by the President (Dr. S. Sherwell of Brooklyn), after which the first day's subjects will be Angiokeratoma of the Scrotum, Raynaud's Disease of the Ears, cases of Hydroa Vacciniforme and Bromide Eruption, a discussion on the Usefulness of Electrolysis in Dermatology, and the Relation of the Epitrichial Layer of the Epidermis to Ichthyosis Congenita. Amongst the numerous subjects announced for the two succeeding days are papers on the Treatment of Erysipelas and on Alopecia.

A QUESTION OF "ISOLATION."—The people of Elson, a village near Portsmouth, are much exercised at a method of "isolation" which certainly has novelty to recommend it. The urban district council requires a site for an isolation hospital, and the action of their committee has opened an old sore. Seven or eight years ago the now deceased local board required a hospital and pitched on this identical site at Elson. A Local Government Board inspector duly made inquiries, and the site was purchased. In 1893 several cases of small-pox occurred, and tents were erected for their accommodation. This brought the military authorities to the fore; they promptly declared Elson out of bounds and hinted at closing the forts in the parish. Such was the local feeling—the tents being "at the very doors" of the people—that without petition the board abandoned the site and advertised for another. The committee of the Gosport and Alverstoke urban district council, which district includes Elson, now recommend, however, that it be once more requisitioned for isolation purposes. Nearly every inhabitant of the village was present at the meeting of protest, and they have unanimously petitioned against a hospital "within a few yards of their doors." The matter, so far as this authority is concerned, is in an initial stage, but the question affects not only a semi-rural but a naval and military population.

A QUESTION OF "ISOLATION."—The people of Elson, a village near Portsmouth, are much exercised over the method of "isolation" which certainly has novelty to recommend it. The urban district council requires a small-pox isolation hospital, and the action of their committee has opened an old sore. Seven or eight years ago the deceased local board required a hospital and purchased the identical site at Elson. A Local Government Board inspector duly made inquiries, and the site was approved. In 1893 several cases of small-pox occurred, and tents were erected for their accommodation. This brought the matter to the authorities to the fore; they promptly declared Elson within their bounds and hinted at closing the forts in the parish. Such was the local feeling—the tents being "at the very doors of the people—that without petition the board ordered the site and advertised for another. The committee of the Gosport and Alverstoke urban district council, which includes Elson, now recommend, however, that a hospital be more requisitioned for isolation purposes. Another inhabitant of the village was present at the meeting of the test, and they have unanimously petitioned against the "within a few yards of their doors." The matter, so far as this authority is concerned, is in an initial stage, but a question affects not only a semi-rural but a military population.

VACCINATION AND REVACCINATION.—We are glad to see that the following document, signed by the vaccination officers of the Whitechapel Union, has been posted throughout the district:—"The Medical Department of the Privy Council advise that all persons who have been vaccinated in infancy should, as they approach adult life, be revaccinated, and the public are therefore earnestly requested to avail themselves of this great and simple safeguard against small-pox. The best time for revaccination is between fifteen and eighteen years of age. But if there is a prevalence of small-pox, or if individuals from personal circumstances are likely to have chances of infection the age of fifteen should not be waited for, especially in the case of young persons whose marks of vaccination are not satisfactory. In circumstances of special danger, everyone past childhood on whom revaccination has not been successfully performed should, without delay, be revaccinated. The Royal College of Physicians also strongly recommends that all persons who have passed the age of puberty and have not been revaccinated since, should be revaccinated. It will thus be seen that it is considered by the two highest medical authorities in the country that every adult person should be revaccinated." We quote this as given in the *Echo*, which calls the notice an "extraordinary document."

MORLEY HOUSE SEASIDE CONVALESCENT HOME FOR WORKING MEN.—The half-yearly meeting of the board of governors of this institution, which is situated at St. Margaret's Bay, near Dover, was held on the 28th inst., in the Memorial Hall, Farringdon-street, Mr. J. A. Dickinson presiding. The annual report and balance-sheet showed that during the past year 798 patients had been received, an increase of 132 over the previous twelve months. A gratifying feature of the report was that in addition to an increase in the subscriptions and donations increased awards had also been received from the Hospital Sunday and Saturday Funds. The report notes with satisfaction the increased favour the Home is obtaining with agencies, there being now associated with the Morley Home (either in connexion with single beds or wards) the following: the City Police, G.P.O. (for London postmen), Gough and Sons, Beckenham and Penge Societies, Hearts of Oak Society, Governors of the Bank of England, Church of England Temperance Benefit Society, and the Improved Industrial Dwellings Company. An account of the opening of the Caxton Wing in May last by the Hon. W. F. D. Smith is also given. The Home is free from debt, but the number of patients seeking admission is growing so rapidly that some steps must be taken in the near future to increase the accommodation. The report was adopted, and the proceedings closed with a vote of thanks to the chairman.

CHARITABLE BEQUESTS.—The *Daily News* states that estate duty has been paid on £259,557 as the value of the personal estate of Mr. William Berry, of 525, Rochdale-road, Manchester, and of Parklands, Durham Massey, Chester, blacking manufacturer, who died on June 8th last. He bequeaths to the Manchester and Salford Street Children's Mission £500; the Altrincham and Bowdon Provident Society at Altrincham, £500; the Altrincham Hospital and Provident Dispensary, £1000; the Manchester Clinical Hospital for Women and Children, £1000; the Manchester and Salford Sick Poor and Private Nursing Institution, £1000; the Manchester Hospital for Consumption and Diseases of the Throat, £1000; the Manchester Royal Eye Hospital, £1000; the Manchester Institution for Diseases of the Ear, £1000; the Society for the Prevention of Cruelty to Children, £1000; Mr. Barnardo's Homes and Missions, Stepney-causeway, £1000; the Manchester and Salford District Provident Society, £1000; Henshaw's Blind Asylum, Old Trafford, £1000; the Southport Convalescent Hospital and Sea Bathing Institution, £2000; the Manchester General Hospital and Dispensary for Sick Children, £2000; the Old Trafford Schools for the Deaf and Dumb, £2000; the Royal National Lifeboat Institution, £2000; the Northern Counties Hospital for Incurables, Heaton Mersey, £2000; the Salford Royal Hospital, £1000; the Boys and Girls' Homes and Refuge and Children's Aid Society, £3000; the Ancoats Hospital, Manchester, £5000; the St. Mary's Hospital and Dispensary, £5000; the Manchester City Mission, £5000; and the Manchester Royal Infirmary and Dispensary, £10,000. All the residue of his property Mr. Berry leaves to his brother Thomas.

HOUSE OF COMMO[NS]

THURSDAY, AUG. 22ND.

Disease in Imported Milk

Admiral Field asked the President of the Board [of] he could take any steps under the law as it [stands] this country against the importation of milk [from] foot-and-mouth disease, pleuro-pneumonia, or o[ther] exist, which were liable to be communicated n[ot] human beings, and were consequently dange[rous] and, if the existing law was defective in this r[espect] further Parliamentary powers in the ensuing s[ession] cope with this acknowledged evil.

Mr. Walter Long replied that if any danger t[o]

Digitized by Google

should arise by reason of the importation of milk he thought he should be able to meet it by the powers given under the Diseases of Animals Act. Questions affecting the health of human beings, however, were for the Local Government Board to consider, not for his department.

On the following day Admiral Field addressed his question to the President of the Local Government Board, and Mr. Chaplin replied that he had no power to prevent the importation of milk from countries where infectious diseases existed, but the matter was of importance, and would not escape his attention.

The Water-supply in East London.

Mr. James Stuart addressed a number of questions on this subject to the President of the Local Government Board

Mr. Chaplin, in the course of his replies, said he was informed by the East London Water Company that the increase in the quantity of water supplied during the month of June last, as compared with the supply during the corresponding month in the two preceding years, was due (1) to an increase of 36,000 in the population since 1893; (2) to the fact that a large number of pipes belonging to the consumers were burst, 50,000 burst pipes having been found between April 20th and June 29th—in many instances the necessary repairs had not yet been carried out; and (3) to the abnormally dry weather of May and June, when garden watering was a source of great waste. The engineer of the company stated that all pipes belonging to the company within the county of London which were damaged by frost or otherwise were replaced or made good by April 8th. He (Mr. Chaplin) had communicated with Major-General Scott, the Water Examiner under the Metropolis Water Act, and he informed him that he had no information which would lead him to doubt the accuracy of the statements of the Company in the matter. He had made inquiries of the several water companies in London as to the number of days' supply represented by the capacity of their storage reservoirs for unfiltered water. The effect of the replies was: East London Water Company, an average of about seventeen days' supply of Lea water; West Middlesex, six and a third days' supply; Grand Junction Company, three and a half days' supply; New River Company, four or five days' average supply; Southwark and Vauxhall, four days' supply; and Chelsea, thirteen and a half days' supply.

Lunacy in Ireland.

Mr. Gerald Balfour, Chief Secretary for Ireland, replying to a question put by Mr. Kenny, said that the increase in the number of admissions of lunatic patients into institutions was attributed by the Lunacy Commissioners in great measure to causes other than an increase of the disease of insanity in its more serious forms. And in their last report they point to the continuously increasing proportion of old-age admissions as confirming this view. At present he had no well-digested information with respect to foreign countries, and was not satisfied that anything would be gained by an international commission. He would, however, consider the matter during the recess.

Local Authorities and Sanitation.

Mr. Chaplin, in answer to Mr. Yerburgh, said that the practice of the Local Government Board had been to refer to the reports of the Assistant Commissioners in connexion with the examination of the annual reports of medical officers of health, and where the reports of the Assistant Commissioners had contained statements respecting cottage accommodation the Board had communicated with the local authority on the subject when it had appeared to them that advantage would be likely to result from such communication. Apart, however, from the reports of the Assistant Commissioners, the Board were accustomed upon the materials furnished by the annual reports of the medical officers of health to draw the attention of the local authorities to matters of sanitary importance in connexion with the housing of the working classes.

Small-pox in London: the Salvation Army Shelters.

Mr. Chaplin said, in reply to a question, that his attention had been called to a report of the proceedings instituted by the vestry of St. George, Southwark, with regard to alleged overcrowding of the Salvation Army shelter in Blackfriars-road. He understood that the case was adjourned and no decision had yet been given by the magistrate in the matter, and he thought therefore that he could not properly make any observations with reference to it. The Local Government Board were aware that a considerable number of cases of small pox had occurred amongst persons who had been received in the Salvation Army shelters. In the early part of last year the Board directed an inquiry as to the arrangements in connexion with these shelters, especially as regards dealing with cases of infectious disease, and at the beginning of the present month he requested that further inquiries should be made by one of the medical inspectors of the Board as to precautionary measures taken at the shelters with a view to the detection of cases of small-pox among the persons admitted. The general result of the inquiry would appear to be that the Salvation Army authorities realised their responsibility in the matter of small-pox, and were anxious to do all in their power to prevent the spread of that disease by means of the shelters. The Local Government Board were not empowered to enforce a medical inspection. Any powers for this purpose, apart from those which might be exercised by the medical officer of health, could only be obtained by legislation. The subject had been receiving his attention, and the question as to an alteration of the law with regard to these and other similar institutions would be considered by him.

FRIDAY, AUG. 23RD.

The Clothing of the Metropolitan Police.

Colonel Howard Vincent asked the Secretary of State for the Home Department whether he would consider, in conjunction with the Commissioner of Police for the Metropolis, the possibility of reducing the issue of tunics to sergeants and constables to one in two years, and supplying in the alternate year a smart serge jacket for use during ordinary day duty in the summer and by police engaged in office or in-door work, as in many provincial forces, and possibly with a lighter headdress than the felt helmet.—Sir Matthew White Ridley replied that the question of supplying the metropolitan police with a lighter headdress and clothing for summer wear had been repeatedly before his predecessors, and the result of their consideration of the matter had invariably been a decision that, on medical and other grounds, the change would be undesirable. He should be willing, however, to give the matter his consideration and to confer with the Commissioner of Police.

Imported Frozen Meat.

Mr. Walter Long said, in reply to Mr. Dunbar Barton, that representations had been made to the Board of Agriculture that there was not proper inspection of the cattle slaughtered in Australia for export as frozen meat to this country, and information was obtained as to the measures taken in certain of the Australian colonies to prevent the export of meat unfit for human food. The information was communicated to the Local Government Board, with whom it would rest to consider whether any further measures for the security of human health in this country were necessary and practicable.

MONDAY, AUG. 26TH.

Vaccination Commission Report.

Mr. Chaplin said in reply to a question that he caused a letter to be addressed to the Royal Commission on Vaccination on Aug. 13th, in which the commissioners were informed that the Local Government Board were strongly impressed with the urgent importance of the final report being made at as early a date as possible. He was informed that the commissioners were now preparing their final report, which would be presented at the earliest possible moment, but he regretted that he was unable to give any more definite information.

Dispensary Doctors in Ireland.

Mr. Abraham asked the Chief Secretary to the Lord Lieutenant of Ireland whether the Local Government Board sanctioned dispensary doctors having the dispensary in their own houses in towns where premises suitable and convenient to the public could be obtained; whether under these circumstances they would sanction a board of guardians surrendering an existing dispensary held on lease at a reasonable rent in order to accommodate the doctor, five minutes' walk being saved him; and whether, in the interests of the ratepayers, they would refuse sanction to such an arrangement if brought under their notice.

Mr. Gerald Balfour replied that the provision of dispensary accommodation devolves upon boards of guardians under Section 8 of the Poor-law Relief (Ireland) Act, 1851, and it is not the practice of the Local Government Board to interfere with the guardians in the selection of premises unless satisfied that the premises are inconveniently situated or otherwise unsuitable for the sick poor seeking medical relief. With regard to paragraphs 2 and 3 of the question the Local Government Board can express no opinion as to the action they might feel called upon to adopt until all the facts of the particular case are placed before them.

Nursing in Workhouse Infirmaries.

In the course of the debate in Committee of Supply on the vote for the Local Government Board, several members called attention to this important subject. Mr. Chaplin, speaking for the Board, admitted that the regrettable cases which had occurred in workhouses of patients suffering from illness owing to inefficient and inferior nursing ought to receive their careful attention. He had already made inquiries on the subject, and he understood that at the present time there was in existence a Workhouse Nursing Association, by means of which nurses were trained and also recommended. He understood, moreover, that many boards of guardians subscribed to the association. The Local Government Board attached great importance to the work of the association, and also to the nursing duties in workhouses by trained nurses. It was also the policy of the Board to discourage as far as possible the nursing of patients by pauper nurses. This had been the general policy of the department, and it was one which he hoped to continue to carry out in the future, realising how important it was that the nursing establishment connected with workhouses should be thoroughly reformed. Sir Walter Foster, the Parliamentary Secretary to the Local Government Board under the late Administration, also took part in the discussion, assuring the House that of late years the subject of the nursing of the sick poor had received a great deal of attention from local authorities in different parts of the country, and that the Local Government Board had not been idle with regard to it.

TUESDAY, AUG. 27TH.

Ventilation of the London Underground Railways.

Mr. Ritchie, President of the Board of Trade, questioned by Mr. Weir, declined to bring in a Bill next session dealing with the ventilation of the underground railways in London. At another sitting of the House Mr. Ritchie had said that if the companies concerned were to consult their own interests they would take steps themselves to deal with what was a subject of general complaint by those who travel on the railways.

The Gresham University Commission.

Mr. Balfour informed the House that legislation with regard to the report of the University of London (Gresham) Commission would be impossible in the course of the present session of Parliament, and he was unable to say what legislative action would be taken by the Government.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.

Notes, Short Comments, and Answers to Correspondents.

EDITORIAL NOTICE.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICE.

"THE LANCET" AND ACCIDENT INSURANCE.

A LITHOGRAPHED CIRCULAR LETTER, emanating from an office in the Strand district, is being sent to members of the medical profession, offering to supply them with THE LANCET, in conjunction with an accident insurance policy. The Proprietors of THE LANCET are in no way connected with the scheme (of which they cannot approve), and were not aware of its inception until their attention was called to it by a reader who had received the circular.

"THERAPEUTIC" FOLK-LORE.

WE have received the following from a correspondent. Fruit, according to orthodox theology, was the source of all our woe. Now, apparently, the same food is the source of every blessing.

"*Lemon Cures.*—Cures chronic bronchitis, diseased lung, and brings back the voice after being lost, also coughs of the longest standing and nightmare. Directions:—Place a lemon whole as you have bought it on the oven top; keep now and again turning it over, in order to keep it from bursting. It becomes heated all round and turns into a strong acid by this process. Then have a cup and fork ready; touch it with the fork, and it will run whole into the cup; stab it well with the fork, drink off the hot juice neat as sharp as possible, go straight to bed, and you will be asleep directly. I was cured in two nights after being given up by the doctor, who said I should linger away the last stage of chronic bronchitis. In my case I had no pain, and was surprised about nine o'clock after breakfast to loose (*sic*) a great quantity of hard stuff in the nature and form of hard gristle, which for the moment quite stunned me, cut in the form of minute squares. I should say I lost a gill and a half. This is 12 years since.

"*Chronic Rheumatism.*—Have 4 woollen socks, a lemon, and a glass of whisky, which is all that is required. If in the higher part of the frame, the head and the shoulders, hold the lemon in the palm of your right hand, still admitting the lemon in the hand. Pull on the 4 woollen socks singly same as gloves till you get on the 4, which is eight. Take a glass of whisky, and the natural heat of the body will draw the disease into the said lemon, discolouring it; if rheumatism, green—different diseases different colours.

"*Bleeding Piles*—Which I conscientiously feel without doubt in my own mind that this form is chronic. ½ lb. best figs placed in a small dish; pour a little water over them, then stew them in the oven. Drink the water in proportion as you eat a fig before breakfast fasting. This never fails."

G. R. P.—Apply to the Secretary, St. Andrews Ambulance Association, 103, West Regent-street, Glasgow. This is only a suggestion, for perhaps the same rule holds good as with the St. John's Association.

ADVERTISING IN THE LAY PRESS.

WE notice in the columns of a lay contemporary an announcement that "Sir Dyce Duckworth, the well-known physician, has gone to America. He intends to be back in this country about Sept 16th." We are too often compelled to reprove practitioners with advertising, or to call attention to their being advertised by injudicious or stupid friends, and we cannot ignore similar occurrences in the case of leaders of the profession, although we feel sure that the objectionable notice has been inserted without Sir Dyce Duckworth's knowledge or leave. The curse of publicity which necessarily attends upon those in any prominent position makes it, perhaps, more difficult for them than for humbler members to avoid this sort of thing, but owing to their position it is of all the more importance that they should take every means to prevent such notices getting into the public press.

To the Editors of THE LANCET.

SIRS,—One has been highly impressed by your just criticisms which have appeared from time to time in the medical journal *par excellence*, THE LANCET, on the occasion of "puffs" of medical practitioners by the lay press. On turning over the leaves a few days since of "Parke's Drug Stores, Limited" (21, Princes-street, Oxford-circus, W.), which has a very extensive circulation among its customers, I was a good deal surprised to read that pages 42 to 45 were devoted to a "Directory of some London Doctors," which comprise the names of many of our leading hospital physicians and surgeons, with their respective residences, as well as specialists of all diseases, from the throat to the anus. Surely, this is a most flagrant form of advertisement, and deserves your severe censure. It is to be regretted that the leaders of our profession should set their younger members such a reprehensible example, when so much has been written condemning medical advertising. It is, however, just possible that these gentlemen may not have sanctioned their names figuring so glaringly as they do in Parke's price list.

I am, Sirs, yours faithfully,

High-street, Putney, S.W., Aug. 21st, 1895. J. FRENCH BLAKE.

"FACING BOTH WAYS."—HOMŒOPATHY, IF PREFERRED!

THE following card deserves a wider circulation than its author designed for it.

"E. W. J. Ireland, Physician and Surgeon, 142, Elizabeth-street. Hours for Consultation: From 9 to 10.30 A.M., and from 2 to 3 and 6.30 to 7.45 P.M. Telephone No. 92.

"N.B.—Dr. Ireland will treat Homœopathically any of his patients preferring to be so treated."

Mr. Ireland is, we believe, an M.B., C.M. Edin., and practises in Hobart, Tasmania. His estimate of medical duty does not seem so high as we should have expected in the graduate of an ancient and famous University. If a patient is to choose his own treatment, where is the use of the medical man's scientific knowledge? If the medical man consents to be guided by the whims of the patient, where is his conscience and his dignity? Even the public will be apt to appraise lightly the judgment and the principles of a practitioner who to please a section of his patients adopts a practice which he does not pretend to adopt for its own sake.

Dr. C. E. FitzGerald.—The work of translation would probably be arduous, but there is no doubt that the book would receive much attention. It is profusely illustrated, and therefore the best plan would be, in the first instance, to approach some leading firm of publishers respecting its reproduction in this country.

Dr. F. A. Watkins.—The Meath Home for Epileptic Women and Children, Godalming, Surrey. This useful institution is sadly hampered by want of funds, and there are very few free beds. See THE LANCET, March 9th, 1895.

Mr. A. J. Morris.—Not if properly cooked, but improper cooking might happen also when a coal fire is used.

A Guardian, late Medical Officer's, letter shall receive attention in our next regular issue.

H. M. K.—Our correspondent must consult his own medical man.

"RAILWAY TRANSPORT FOR INVALIDS."

To the Editors of THE LANCET.

SIRS,—In reply to a letter signed "Railway" which appears in the current issue of THE LANCET, I beg to state that I was the successful competitor for "the best method." On your correspondent communicating with me I shall be pleased to give some particulars of the method. Also, if I might be allowed space in your columns, I should be glad to give full details of the method, which is as simple as it is absolutely effectual. I am, Sirs, yours obediently,

HAYDN BROWN, L.R.C.P. Edin.

12, St. Charles-square, North Kensington, W., Aug. 24th, 1895.

A STRANGE REQUEST.

THE questions addressed to us week by week are of a truly encyclopædic nature and the commissions we are asked to execute of a most varied and curious character. The following is perhaps worthy of record:—

"London LANCET.—Mr. Editor,—I ask you to place this letter in the hands of some man or company of men in your city of London who will sell me a wig for my mo ther, who is sixty-five years of age. The wig shall be full size with some gray hairs in it, so that it shall be appropriate for a person of her age. The wig shall be strictly first class and a good one. Send me prices and instruction for measurement."

The letter, which comes from America, is duly signed by "—— ——, M.D." We omit the name, as the letter is doubtless a hoax. Can it be that the writer is aware that from a hairdresser's window facing our office a gentleman whose wig is changed nearly every day has from time immemorial, as it were, fixed his glassy stare on our editorial room? If this information is of any assistance to our correspondent he is welcome to apply to the "Dummy" in question.

MESSRS. FRANCIS NEWBERY AND SONS, of 1, and 3, King Edward-street, E.C., write in reference to our articles on the British Medical Association Museum that their exhibit was made by them on behalf of Messrs. William R. Warner and Co., New York and Philadelphia.

Post Mortem.—We do not think that there is any definite rule; but probably most principals would allow the locum-tenent to take the fee.

Subscriber.—Our correspondent should communicate either with the clerk or chairman of the board of guardians.

"THE TITLE OF 'DR.'"

To the Editors of THE LANCET.

SIRS,—Your correspondent, Mr. J. B. Pike, looks only at the subject in a selfish way. If Mr. Pike, and those like unto himself who have so long cast a hungry look at the title of "Dr." and have ever been desirous of possessing the same, would but fulfil the necessary conditions requisite for possessing the same, then the feeling of "irritation" and "chronic desquamation with a tendency to itching" complained of would have its causation removed, and the only honest and legitimate treatment prescribed. No amount of sophistry can gainsay this—namely, that to be a doctor one must be a doctor of something, be it medicine, law or theology; without such no person is entitled to the term "Dr." Mr. Pike says the matter could be settled (1) by a consensus of qualifying bodies; (2) by friendly (*sic*) legal action; (3) by obtaining highest legal opinion. I reply that it could not, but only by passing the necessary training and examinations. To me it is incomprehensible how any medical man can wish to appropriate that which he is unentitled to. In medicine the title "Dr." exclusively and incontestably belongs to graduates possessing the degree of M.D., so that it certainly is not honourable for medical men not possessing that degree to style themselves or desire to appropriate, the title "Dr." As for being called and styled "Dr." by courtesy, the idea is absurd and ludicrous in the extreme. Fancy for courtesy's sake expecting and desiring what does not belong to one, thereby rendering the person artificial and more like a fool than an educated man. Again let me recommend those gentlemen who desire the title of "Dr." to take the M.D. or go without it.

I am, Sirs, yours truly,

Aug. 28th, 1895. M.B., C.M.

*** We have received several other communications upon this subject, for which we cannot find room. One correspondent, who has failed to understand us (which has not stood in the way of a desire to criticise our recent leading article very severely) asks: "..... What is there more calculated to mislead and puzzle the general public than trying to explain to them what they never knew, and never will know, and never care to know .....?" We ask with him, What? Our article, however, was not addressed to the public, but, as is our invariable custom, to the profession, and all the letters to which we were to a certain extent replying, save one, were from medical men. This correspondence must now cease.—ED. L.

Consanguis.—THE LANCET, vol. ii. 1883, p. 88; THE LANCET, vol. ii. 1885, p. 680; Brit. Med. Jour., vol. i. 1887, p. 1145; "The Marriage of Near Kin," by A. H. Huth (Longmans, 1887).

W. E.—We never prescribe; our correspondent must consult his own medical man.

Mr. T. Caton, jun.—We know nothing whatever of the matter in question.

M.B., C.M.—Our correspondent has forgotten to enclose his name and address.

COMMUNICATIONS not noticed in our present number will receive attention in our next regular issue.

MIDWIFERY DIPLOMAS.

Truly Qualified.—The right of any registered practitioner to practise midwifery has never, as far as we know, been questioned. The essence of the Act of 1886 was in enacting that henceforth no person should be registered who was not qualified in the three branches of medicine, surgery, and midwifery—midwifery for the first time being placed, as a condition of registration, on a level with medicine and surgery. Even a midwife can recover her fee in a court. 2. The regulation in regard to a pupilage for six months in the fifth year is permissory only, not binding.

LONDON: SATURDAY, SEPTEMBER 7, 1895.

AN ADDRESS TO MEDICAL STUDENTS.

THE period of year has once more come round at which it is our custom to address some words of advice to those who are about to commence their medical education by entering as students at some one of the regular medical schools. We propose, in the first place, to say a few words as to certain considerations that we think should be borne in mind before any final decision to adopt a medical career is reached. With many the question for preliminary determination will be as to how the profession of medicine stands regarded merely as a career, as a means of earning a living by work, by the employment of whatever powers each one may happen to possess. Considering the matter from this point of view only, it appears to us that our profession, as far as the great body of its members is concerned, has advantages to offer by no means inferior to those held out by any of the other learned professions, or, indeed, to those of any calling likely to attract a man of liberal education. It has at times been somewhat the fashion to make light of these advantages; but to do so appears to us to be a mistake. While we should be the last to say that anyone does wisely in choosing to enter the medical profession if his chief or only desire is to make money for the sake of making it—undertaken in a purely sordid spirit medical work leads to nothing but disappointment—yet, on the other hand, ours is a profession in which work well done, done with the determination to do it as well as lies in the power of the worker, seldom or never fails to bring with it that reasonable degree of affluence that will content a man who desires what is sufficient, but who has no overweening passion for what is superfluous. It is, no doubt, quite true that some large fortunes, comparatively speaking, have been made by members of our profession. Exceptional ability, joined to exceptional opportunity, with exceptional powers of mental and physical endurance, may naturally be expected to produce results, both pecuniary and otherwise, of an exceptional kind. There is always plenty of room in the front rank of every profession. These, however, are only the exceptions which prove the rule. The rule is that, provided he is not too heavily handicapped by disadvantages of circumstance or disposition, it is generally a man's own fault if he fails to make a living as a medical practitioner. So much for an aspect of the matter the importance of which it would be only affectation to ignore. We pass on to the consideration of some of the elements of character more especially needful in the profession of medicine. The most necessary of all is the possession of that quality—using the expression in its broadest sense—known as presence of mind. It must be remembered, when all has been said, that ours is essentially a practical profession. It is, no doubt, highly desirable to start with as large a stock of knowledge as possible. It is essential to have learnt the chief facts structure of the body in health and to hav various changes, both macroscopic and mic that structure undergoes under the influence have studied the functions performed by the d in a state of health and the alteration in t occurring under various morbid conditions; learnt the therapeutic measures recommended rities as applicable according to the particular of each case. All this is very good as far as essential, however, not only to possess the kno have the power of applying it when it is wan practice is largely a labour of emergency. Th never knows at what hour of the day or nig called upon, or what he may be required he is a learned man merely, and nothing el possible that he may be able to write an admi of the etiology, pathology, symptoms, diagnos and treatment of, for instance, scarlet fever, t fail to recognise a case of it when it comes b may know his text-book of surgery, perhaps, a and yet be unable to put up any common frac he may be able to enumerate the characteris all the rare forms of contracted pelvis, and y be the cause of rupture of the uterus from to distinguish between a shoulder and a sentation. In short, as has been well presence of mind he is in the position of with a gold nugget or a £100 note in is unable to get change. There is a young surgeon who went out with two d was shot in the thigh. Some time afte assistance arrived, the surgeon was found knee of blood beside the wounded man, by that ti and making pressure with his thumbs two inc wound. The story affords a good illustration sity of presence of mind. No doubt the have known the position of the main bloodves the lower limb, he may very probably have d fully, and may even have gained the gold anatomy class; but either from a constitutiona or from his mental balance being upset by th on his faculties, he was unable to use his as to save his patient—he lacked presence student would do well to consider carefully respect of this literally vital quality before dec the medical profession. Again, patience and readily sympathising with the troubles of other almost indispensable to the medical man. A doubt, acquire the appearance of the former, originally possess it, by a habit of *self-co* counterfeit sympathy is rarely a satisfactory Yet even from a purely professional point o pathetic attitude is not unimportant. Much th tioner ought to know in the interest of the p withheld if the former's attitude is too cold an regards his patient too much in the light of a case. Many otherwise eminent men have not reproach in this respect. They have, however spite of, rather than because of, their deficien some other facts incidental to the life of a me

Digitized by Google

should be clearly understood in the beginning, if disappointment afterwards is to be avoided. A man who looks forward to a great deal of leisure in his life had better turn his attention elsewhere; if he desires to have two or three months' holiday in the course of the year, his destiny is evidently to become a barrister or a schoolmaster, for there is extremely little chance of his getting anything of the sort in the medical profession. The practitioner never knows when his day's work is done. If he is fairly successful he may very probably have to work twelve hours a day and very possibly have to sit up for part, or for the whole, of the succeeding night, and yet do his work as usual on the following day. There is no trades-union limitation of the medical day. This suggests another aspect of the matter. It is obvious that a man cannot long stand the fatigue of busy practice unless he is the fortunate possessor of a sound constitution and good general health. If he has these at starting, it will need some care to retain them. Overwork, mental and physical, is a bad thing, but it may be adequately combated if the fact that it is overwork be recognised in time, and assistance be obtained so as to reduce it to what is felt by the individual to be reasonably within his strength. Overwork persisted in has in every vocation too often led insidiously to the excessive use of stimulants to enable the jaded mind and body to hold on a little longer. Once a man, whether in our profession or in any other, has constant recourse to stimulants whenever he is overworked, his fate is rarely doubtful. Those who have succeeded best in practice have generally had the faculty of putting the patient at his ease. If they have been in a hurry they have nevertheless had the tact to conceal it, and have avoided all appearance of cutting short what the patient has to say. To be a good listener is a valuable characteristic, perhaps more so even than the faculty of talking well. It is not necessarily a mere passive endurance, for the patient may be unconsciously directed in his conversation, so that he tells of what really has a bearing on his case. There is another matter which it may not be inappropriate to touch upon. It has been for generations the tradition and glory of the profession of medicine that its members have always been ready to give their services without fee or reward of any kind to those whose circumstances required it. It will rest with those who are now about to enter the profession to carry on this honourable tradition, though the doing of it will not rarely add very materially to their labour, and involve an additional strain on faculties that are already fully employed.

We have mentioned very briefly some of the advantages and some of the disadvantages belonging to the profession of medicine, as well as some of the qualities without which the pursuit of that profession can scarcely be otherwise than labour and sorrow. It rests with each one to decide for himself whether the advantages outweigh the disadvantages, and whether he feels within himself that natural aptitude which may fairly be regarded as constituting a vocation to the profession. To those who have carefully weighed the matter, and feel attracted towards the profession by an irresistible fascination, we offer our warmest sympathy and congratulations. To our thinking there is no finer field for the exercise of the best powers implanted in man, both intellectual and moral, than is to be found in the practice of medicine. The material for investigation is practically inexhaustible, problems innumerable of infinite variety and all degrees of complexity await solution; and those who are now starting at the beginning as students in the narrower sense of the word will, if they are wise, find that their curriculum is not limited to a period of five years, but that the spirit of investigation accompanies them across the magic boundary that they will cross on becoming qualified members of our profession, and will, indeed, be their companion throughout life itself. Students we have all been at the beginning, and if we would act fairly by ourselves, as well as by our patients, students we should remain to the end.

Having determined to enter the medical profession, and passed some one of the necessary preliminary examinations in general education, the student will have to choose his medical school, if, indeed, circumstances have not already decided this point for him. Where the choice is an open one, and, as in London, there are a large number of schools from which to choose, the selection may not be an easy matter.

To a man of only moderate ability some one of the smaller schools presents the doubtful attraction that his mediocrity may have the chance of passing for something more than its intrinsic value; whereas in the larger and more popular schools it may easily obtain for him a relatively lower and more insignificant place than his actual merits may deserve. As regards these alternatives the latter is probably to most a more salutary experience than the possibly fictitious prominence that may be incidental to the former. In this instance it is better probably to be a minnow among Tritons than vice versâ. What we have said applies more particularly, however, to the school work as distinguished from the clinical work done at the hospital. It is difficult or impossible to say till a student actually begins his work in the hospital what his clinical ability may prove to be. It is no uncommon thing for a student, who has made little or no mark in his earlier work, to develop an entirely unexpected aptitude when the scene is shifted to the wards of the hospital. Other things being equal, however, the man of average ability has a better chance of obtaining resident appointments in the hospital at some of the smaller schools than where, owing to the large number of students, these valuable posts can only be looked for by the brilliant few. Yet every student should do his utmost to hold some one at least of the resident appointments in the hospital connected with his medical school. If he cannot do this, the next best thing is to become house surgeon or resident medical officer at some hospital not attached to a school before actually settling in practice. It should be remembered that a large school means a school at which there are a large number of students, and does not necessarily mean that the hospital connected with the school is a large one. Sometimes both actually and relatively to the number of students the contrary is the case, and a large school has only a small hospital available for its clinical teaching. In such cases the authorities generally insist that, although their hospital may be a small one, they make up for it by a zealous determination to make the very most of their limited material; while the authorities at those schools to which very large hospitals

medicine. The material for investigation is practically inexhaustible, problems innumerable of infinite variety and all degrees of complexity await solution. Even those who are now starting at the beginning of the curriculum in the narrower sense of the word will, if they are wise, find that their curriculum is not limited to a period of years, but that the spirit of investigation and inquiry carries them across the magic boundary that they will have passed, becoming qualified members of our profession and friends indeed, be their companion throughout life itself, as it is if we have all been at the beginning, and if we would succeed fairly by ourselves, as well as by our patients, we should remain to the end.

Having determined to enter the medical profession and passed some one of the necessary preliminary examinations in general education, the student will have to choose a medical school, if, indeed, circumstances have not already decided this point for him. Where the choice is open to one, and, as in London, there are a large number of schools from which to choose, the selection is not an easy matter.

To a man of only moderate ability [illegible] smaller schools presents the doubtful attraction that mediocrity may have the chance of passing for more than its intrinsic value; whereas in the larger and more popular schools it may easily obtain a relatively lower and more insignificant place than its actual merits may deserve. As regards the latter, the latter is probably to most a more salutary than the possibly fictitious prominence incidental to the former. In this instance probably to be a minnow among Tritons than What we have said applies more particularly the school work as distinguished from done at the hospital. It is difficult till a student actually begins his work in his clinical ability may prove to be. thing for a student, who has made little earlier work, to develop an entirely when the scene is shifted to the wards Other things being equal, however, has a better chance of obtaining the hospital at some of the smaller owing to the large number of students, can only be looked for by the brilliant student should do his utmost to hold the resident appointments in the hospital his medical school. If he cannot do thing is to become house surgeon or at some hospital not attached to a settling in practice. It should be remembered school means a school at which there students, and does not necessarily connected with the school is a large one. actually and relatively to the number trary is the case, and a large school pital available for its clinical teaching. authorities generally insist that, although be a small one, they make up for it by tion to make the very most of their limited the authorities at those schools to which

are attached naturally make the most of this circumstance, and point to it as ensuring the greatest amount of clinical experience obtainable in a limited time.

We would urge on students the importance of regular attendance on their various courses of lectures, both systematic and clinical, and at the proper period arranged for such attendance in the curriculum. It is often said, and with some degree of plausibility, that attendance on lectures is of little use, because everything to be heard there can be got out of books. That is true, no doubt, if the student can suppose himself in the position of a master of the particular subject in question, familiar with the whole, or the principal part at all events, of the literature of the subject, and therefore knowing exactly what books to go to for his information, and what to extract from them when he has got them. The lecturer is familiar with the whole of his subject, and if the student attends his lectures regularly and intelligently he has the advantage of having the facts presented to him in their proper relation and in their true perspective. If the student neglects his lectures, and attempts to get up his work from books alone, he is sure to misunderstand much of what he reads, and to waste time in puzzling over some probably unimportant detail when he should be studying some great principle, leaving the points of detail to be dealt with afterwards. He has often no sort of perception of the relative importance of the various things of which he reads. Some lecturers, of course, have the happy faculty of making their lectures interesting in a greater degree than others, but, even if the student feels inclined to be critical in this matter, he will do well not to miss lectures. The effect of doing so is to some extent demoralising, and is too often the forerunner of idle habits, the consequences of which will become fatally manifest when examination time comes round. The question of note-taking at lectures is one of some difficulty. Generally we think it is a mistake to try to take down practically everything the lecturer says. It is not easy to do so, the attempt to do it is often unsuccessful, and after a time not infrequently the whole thing is given up in disgust. However, we think that it is a good thing to take some notes; but they should be short, and as far as possible illustrated by such diagrams made by the lecturer as are not to be found in the text-book the student reads. Of course, in the case of practical work it may be necessary to take down exactly the details of how this or that is to be done. Such notes, however, need not generally be very long. Teachers and lecturers always afford their pupils the opportunity of asking questions, a privilege they should freely avail themselves of as occasion arises. There is, however, a type of student familiar to many of us—the student who asks questions, not, it is to be feared, really to obtain information, but rather, and generally after reading up some portion of a subject, with the apparent object of either puzzling the lecturer, or showing off how much he himself knows. That sort of questioning is closely related to "heckling," and as it can serve no useful purpose the very appearance of it should be scrupulously avoided. It is well for the student to endeavour to verify as much of his teaching as he can—to hear, feel, and see for himself the things of which he reads. Things so learnt are fixed in the memory more permanently than is possible otherwise. We may, in concl on students the desirability of maintaining a go bodily health. Speaking generally this is not matter. Early to bed and early to rise is prove for most of us. It is especially desirable to a sively long hours of reading, and to make a poin sufficient physical exercise. The authorities a our schools have made it their business to provi for football, cricket, and athletic sports. strongly impress on even the "hardest readers" bility of cultivating their physical powers, which c quite well without in any way neglecting mo work. Industry, perseverance, and moderati things will rarely fail to bring their rewar season—that is to say, in the present instance, tion to practise at the end of the five years' curric

THE STUDENT'S LIBRARY AND ITS U

ALL who follow the medical profession must for ever—students as much in the fifth yea curriculum as in the first; students as much at their life's work as when confronted with th patients. From every case for the real physici genuine surgeon a lesson has to be drawn: per point arises, perhaps only a point confirmatory of been previously familiar; but in either instance worth knowing has to be learned. And this the great difference between book-learning and th that is the outcome of practical observation. T extent the need for book-learning may be fini a great extent this need is modified by the ic of the individual. But no man from the mo he places his foot on the lowest rung of the medicine can dispense with observation, or the observation. This need is never finite. A cer ness in the detection of and a certain facili reading of the meaning of symptoms and sig influence of family history and environment ar some in an extraordinary degree; but most certa any man, being gifted in this fortunate manner, think lightly of, perhaps to forego, some of the observation, in the end he will be the worse talents. He will make errors, and will speedily self, and others will as speedily know him, to be a and unreliable, albeit occasionally brilliant, adv book-learning there is a substitute—practical practical work there is no substitute.

And this difference between book-learning learning that is the outcome of practical work and of all opportunities for observation precisely define method of using books. They are to be employe ever way will best assist in practical work. They to this end only. But all cannot employ books i way. Their use must vary immensely with the k student's mind and the habits of work which he readily conduce to the sure and speedy acquisitio ledge. So that in the selection of a text-book, matter of great importance to the student, nc large number and variety of works render the cho ingly difficult, but infallible advice cannot be give

Digitized by Google

counsel to one man will be less valuable to another. In the appended lists of the standard text-books we have endeavoured by brief general remarks to divide the books more or less into three classes—two comprising books specially designed to assist the student in his examinations, being elementary or comprehensive works required respectively for pass or honour examinations; while the third class includes books of reference not designed to be exhaustively read by anybody, but rather to be consulted as a second or elucidatory opinion, where anything in the text-books proper seems obscure or incomplete. But the use that the student will be able to make of these three classes of books will vary entirely with his order of mind. To one man the small elementary book may be well-nigh sufficient reading. He will be able to use it as the skeleton of his knowledge, and will endow it with tissues and life from his personal observation, by practical courses in his school, by clinical work in the wards, and by thoughtful attendance at lectures. This is the student into whose work books do not largely enter. But inasmuch as it is easy to examine fairly and thoroughly upon book-work, while it is difficult to lay down proper standards and discover adequate tests for the appraisement of practical work, the result of examinations must more or less depend upon the ability of the student to answer somewhat in text-book language questions framed somewhat upon text-book lines. Therefore it will be well for the student whose practical order of mind enables him, as it were, to write his own text-book by grafting his practical work on to an elementary manual, to revise his knowledge before entering for an examination by the light of a first-class text-book. This is the best and most feasible way of combining books and practical and clinical work for the formation of a medical education. But it is not in the power of every student to obtain an education in this manner. Practical work is easier to some men than to others, and lectures mean more to some men than to others. The receptive man will benefit by teaching which only arouses opposition in the critical man. The reading of a large text-book by the critically-minded man—the man whose first impulse on hearing a fact is to doubt it or the deductions from it—may very often be the best way in which such a man can gain a knowledge of his subject. He gets an all-round look at it, and though he may not entirely understand everything that he reads, he will obtain a general familiarity with this topic, and see the fallacy of the objections which rise in his mind. The bald statements for which alone the small manual can find room would arouse in him nothing but opposition, and he will be well advised to go straight to the big book where the explanations are included with the facts. But he *must* supplement his wider range of reading with as honest and as earnest a course of practical work as his less literary fellow-students. When confronted with his examination he will find, as hundreds of the most promising students of medicine have found to their considerable discomfiture, that practical work is absolutely necessary, that without it book-work is as nothing, that even to pass in the written part of the examination (for which he feels so amply equipped) will be almost impossible unless his knowledge is fortified and made alive by some measure of practical experience, and, lastly, that no amount of book-work will ever enable him to answer questions by word of mouth.

The short notes upon well-known text-books which follow will enable the student to ascertain the scope of each work, and, with the assistance of advice from his lecturer, he will be able to decide which book is most likely to suit him—that is, which book will best enable him to obtain full benefit from his practical work. He will not be able, perhaps, to decide this point at once; if he is just beginning his career he cannot know for certain in which direction difficulties will assail him. But those are the points we desire to make for his information and encouragement: firstly, all good sound text-books have their place, for knowledge presented in one form to one man is more easily digested if presented in another form to another man; secondly, he must not be disheartened if books, or a particular book, seem to mean more to a fellow-student than they do to him. It is natural that this should be so. If one student finds it difficult to follow the arguments of the larger treatises it is more than possible that to him all sorts of practical work will come as an illuminant. If another man finds that practical work wearies him and puzzles him, although he is earnestly, honestly, and conscientiously desirous of going through his proper course and learning all that it should teach him, it is quite possible that what he requires is a general grasp of his subject, a sort of broad outline of it which would give a meaning to the details that he finds it so wearisome to acquire. It is unnecessary to say that our list of books might be considerably extended. It would be so if we had designed to make it exhaustive. But we do not suggest that the books which we mention are the only ones the students can read with advantage. His regular course of reading will be dictated properly by advice from the lecturers at his school, and, in a measure, by the prevalent fashion at that school. We have only intended to place before him succinct information that shall guide him in his choice, while pointing out to him that all educational books are but a means to an end, and that end is practical knowledge.

ANATOMY.

The standard text-books on Systematic Anatomy are Quain's and Gray's. Both of these have been recently brought up to date. Quain's is the more scientific work and is, indeed, the most advanced and comprehensive treatise on the subject in the English language, if not in all languages. Its morphological, histological, and visceral anatomy is unequalled. The volume on Embryology by Professor E. A. Schäfer is the clearest and best history of development with which we are acquainted. The work is now published in separate parts.

Quain's (Jones) Elements of Anatomy. Longmans and Co. The tenth edition. Edited by EDWARD ALBERT SCHÄFER, F.R.S., Professor of Physiology and Histology in University College, London; and GEORGE DANCER THANE, Professor of Anatomy in University College, London. In three volumes. Vol. I., Part I. Embryology. By Professor Schäfer. Illustrated by 200 Engravings, many of which are coloured. 9*s.* Vol. I., Part II. General Anatomy or Histology. By Professor Schäfer. Illustrated by nearly 500 Engravings, many of which are coloured. 12*s.* 6*d.* Vol. II., Part I. Osteology. By Professor Thane. Illustrated by 168 Engravings. 9*s.* Vol. II., Part II. Arthrology, Myology, Angiology. By Professor Thane. Illustrated by 255 Engravings

Digitized by Google

many of which are coloured. 16*s*. Vol. III., Part I. Spinal Cord and Brain. By Professor Schäfer. Illustrated by 139 Engravings. 12*s*. 6*d*. Vol. III., Part II. The Nerves. By Professor Thane. Illustrated with 102 engravings, many of which are coloured. 9*s*. Vol. III., Part III. Organs of the Senses. By Professor Schäfer. Illustrated by 178 Engravings. 9*s*. The remainder of the third volume, dealing with Visceral Anatomy, is in preparation.

Anatomy, Descriptive and Surgical. By HENRY GRAY, F.R.S., late Lecturer on Anatomy at St. George's Hospital. The thirteenth edition. Re-edited by T. PICKERING PICK, Surgeon to St. George's Hospital, Member of the Court of Examiners, Royal College of Surgeons of England. Thirteenth edition. 36*s*. London: Longmans and Co. With 636 large Woodcut Illustrations, a large proportion of which are coloured, the arteries being coloured red, the veins blue, and the nerves yellow. The attachments of the muscles to the bones in the section on Osteology are also shown in coloured outline. Royal 8vo. 36*s*.—*Gray's Anatomy* occupies a place only second to Quain's. In popularity it is doubtful if it does not actually precede its larger rival, and for mere everyday work it has points of superiority.

Human Anatomy: a Treatise by various Authors. Edited by HENRY MORRIS, M.A., M.B. Lond., F.R.C.S., Surgeon to, and Lecturer on Surgery at, the Middlesex Hospital. Royal 8vo, with 791 Illustrations, nearly all original, and many of them in several colours, 40*s*.—This is an excellent work. We may mention especially the description of the peritoneum, in which the arrangement of that complicated structure is set out with admirable clearness. (In one volume or in three parts.) 1893. London: J. & A. Churchill.

The Anatomy of the Joints of Man. By HENRY MORRIS, F.R.C.S. 1879. J. & A. Churchill.—This is perhaps the most complete book on the subject yet published. The work is fully illustrated, and many of the illustrations are in colour. Besides the bones, ligaments, and synovial membranes, the various features connected with the arterial and nervous supply of the joints, bursæ, and the muscles which act upon the joints are very thoroughly dealt with.

A Text-book of Human Anatomy: Systematic and Topographical. By ALEXANDER MACALISTER, M.A., M.D., F.R.S., F.S.A., Professor of Anatomy in the University of Cambridge, and Fellow of St. John's College, Examiner in Human Anatomy, University of London. Includes the Embryology, Histology, and Morphology of Man, with special reference to the requirements of Practical Surgery and Medicine. One vol. 1893. 816 Illustrations. 36*s*. London: Charles Griffin and Co.—It is in many respects the most important work on the subject that has appeared in recent years, being thoroughly comprehensive, lucid, and up to date.

Wilson's Anatomist's Vade-Mecum. Eleventh edition. By HENRY E. CLARK, M.R.C.S. Eng., F.F.P.S. Glasg., Examiner in Anatomy, F.P.S., and Professor of Surgery in St. Mungo's College, Glasgow. Crown 8vo, with 492 Engravings and 26 Coloured Plates. 18*s*. 1892. London: J. & A. Churchill.

In Practical Anatomy the student has the choice of text-books by Ellis, Heath, Cleland, and Cunningham. The favourite dissecting-room manuals are probably those of Ellis and Cunningham.

Ellis's Demonstrations of Anatomy, as edited by THANE, have been studied by generations of disse for accuracy and thoroughness leave nothing to be *Cunningham's Dissector's Guide* is a very clear, w book, and fully illustrated. It has the advantag published in separate volumes.—*Heath's Practica* is a smaller work, clearly written, and formir pendious introduction to the subject.—*Professor Directory for Dissection* is purely a guide, and as and cheap and contains full practical directio dissector it will be found most useful in the room.

Demonstrations of Anatomy. By GEORGE VIN F.R.C.S., late Professor of Anatomy in Universit London Eleventh edition. 1890. pp. 782. London: Smith, Elder, and Co.

Heath's Practical Anatomy. Edited by W. A F.R.C.S. With 329 Engravings. 1893. pp. London: J. and A. Churchill.

Dissections Illustrated. By C. GORDON BRODIE A graphic handbook for students of anatomy; 7 Plates and 37 Diagrams. London and New York: and Co.—This is an admirable book and shou place in every student's library.

Directory for Dissection. By Professor M.D. Ed. Third edition. 1888. pp. 191 3*s*. 6*d*. Smith, Elder, and Co.

The Dissector's Guide. By Professor D. J. CUN M.D., LL.D., D.C.L. Edin., D.Sc. Dublin, F.R.S. Parts. Edinburgh: O. J. Thin.

Applied Anatomy may be studied from the Treves, Bellamy, Holden, or Maclachlan.

Holden's Landmarks, Medical and Surgical, lik work, is distinguished by its clearness of arrange correctness of detail. It thoroughly justifies its in every way.—*Treves' Surgical Applied Anatom Guide to Surgical Anatomy* by EDW. BELLAMY a general use in our schools. The former is partic of information, conveyed in such a way that it i "stick" in the student's memory.—*Maclachlan's Anatomy* is better known in Scotland. It is a and comprehensive work.

On Osteology as a separate subject *Ward's O Osteology* will be found wonderfully accurate in its details.

Holden's Osteology is distinguished alike for i English and its excellent illustrations.

Landmarks, Medical and Surgical. By LUTHER F.R.C.S. Fourth edition. 1888. 3*s*. 6*d*. Londo Churchill.

Surgical Applied Anatomy. By F. TREVES, pp. 574. London: Cassell and Co. 1894.

Human Osteology. By LUTHER HOLDEN, Edited by Professor Stewart. Seventh edition. Plates. 16*s*. London; J. & A. Churchill. 1887.

Tablets of Anatomy. By THOMAS COOKE, F These tablets are designed to fix the student's know to help him to retain what he has acquired in either from the part or from the text-books. For rapid revision of work they are excellent. London: Longmans, Green, and Co.

Digitized by Google

PHYSIOLOGY.

Text-book of Physiology. By Professor MICHAEL FOSTER, M.D., F.R.S. Four parts. pp. 1550. With an Appendix, *The Chemical Basis of the Animal Body*, constituting a separate volume of 270 pages, by A. SHERIDAN LEA, D.Sc., F.R.S. The best English text-book of the subject; suitable for students preparing for higher examinations. Deals with histology as well as with physiology proper. The parts can be bought separately. Part I. The Blood, Tissues of Movement, and Vascular Mechanism, 10*s.* 6*d.* Part II. The Tissues of Chemical Action and Nutrition, 10*s.* 6*d.* Part III. The Central Nervous System, 7*s.* 6*d.* Part IV. The Tissues and Mechanisms of Reproduction, 10*s.* 6*d.* Appendix, 7*s.* 6*d.* Sixth edition. London: Macmillan and Co. 1893.

An Introduction to Human Physiology. By AUGUSTUS WALLER, M.D., F.R.S. The best manual of medium size; a thorough and attractively written exposition of all departments of physiology proper; well suited to meet medical and other examinations in the subject, but containing very little histology; concise; excellently illustrated; moderate in price. Second edition, 1893. pp. 630. London: Longmans, Green, and Co.

Human Physiology. By Professor LANDOIS. Translated and edited by WILLIAM STIRLING, M.D., D.Sc. Two vols. pp. 1120. Useful for reference; not quite suitably arranged for the student, but containing all the information he can desire to know. Two vols., 42*s.*, with 845 illustrations. Fourth edition. London: Charles Griffin and Co. 1891.

Text-book of Physiology. By JOHN GRAY MCKENDRICK, M.D., F.R.S. A large work, containing in some directions more than the student requires, but a first-class treatise. Two vols. Edinburgh: Maclehose and Sons.

Kirkes' Handbook of Physiology. Edited by MORRANT BAKER, F.R.C.S., and VINCENT HARRIS, M.D. Still one of the best books of smaller size; contains much histology as well as physiology proper; very thoroughly revised in the last edition. Thirteenth edition. London: J. Murray. 1892.

Manual of Physiology. By G. F. YEO, M.D., F.R.S. A good book, somewhat smaller than the foregoing; brought up to date in the last edition. Third edition. London: J. & A. Churchill. 1893.

Elements of Human Physiology. (Student's Guide Series.) By ERNEST H. STARLING, M.D., M.R.C.P., Joint Lecturer on Physiology at Guy's Hospital. Second edition. Crown 8vo, with 94 engravings, 6*s.* 6*d.* London: J. & A. Churchill. 1895.

Physiology for Beginners. By Professor MICHAEL FOSTER, M.D., F.R.S., and LEWIS E. SHORE, M.A., M.D. A capital little book, forming a good introduction to Foster's "Text-book" or to Waller's Human Physiology. Extremely clearly written and thoroughly illustrated. Not sufficient by itself to meet the requirements of medical examinations in physiology or histology. 3*s.* Macmillan and Co. 1894.

PHYSIOLOGICAL CHEMISTRY.

A Text-book of the Physiological Chemistry of the Animal Body. By ARTHUR GAMGEE, M.D. Edin., F.R.S. Two volumes at present issued. Vol. I., Blood, Muscle, and Nerve; Vol. II., Digestion. The best manual on the subject, but only suitable for advanced students. Vol. III. still wanting. The volumes can be bought singly, 18*s.* each. London: Macmillan and Co. 1892.

Text-book of Chemical Physiology and Pathology. By Professor W. D. HALLIBURTON, M.D., F.R.S. An excellent manual for all students. Profusely illustrated. One vol. 8*s.* London: Longmans, Green, and Co. 1891.

The Chemical Basis of the Animal Body. By A. SHERIDAN LEA, D.Sc., F.R.S. A first-rate treatise, constituting an appendix to Foster's Physiology. Smaller, less illustrated and less expensive than either of the foregoing. contains very complete references to original papers. One vol. pp. 270. 7*s.* 6*d.* London: Macmillan and Co. 1892.

HISTOLOGY AND EMBRYOLOGY.

Some physiological text-books deal with Histology sufficiently fully for the pass examinations of the medical student; such books are Foster, Landois, and Kirkes (see above). Special treatises are:—

The Elements of Embryology. By Professor MICHAEL FOSTER, F.R.S., and the late Professor FRANK BALFOUR, F.R.S. Second edition, revised. pp. 470. 1893. Eminently practical; the best book for those examinations in which practical work and manual skill in the subject are required.

Practical Physiology. By Professors MICHAEL FOSTER, F.R.S., and J. N. LANGLEY, F.R.S. Fifth edition. An excellently selected series of laboratory exercises with full instructions to the student. Both, London: Macmillan and Co.

Outlines of Practical Physiology. By Professor WILLIAM STIRLING, D.Sc. Third edition. 1895. Thoroughly revised and partly rewritten, with additional illustrations. Includes chemical and experimental physiology and references to practical medicine; histology not included; the best students' book on the subject; full of information, and beautifully illustrated. — *Outlines of Practical Histology.* Second edition. 1892. Companion volume to the above, and equally good; copiously illustrated. Both, London: Charles Griffin and Co.

CHEMISTRY AND PHYSICS.

Chemistry: General, Medical, and Pharmaceutical. By JOHN ATTFIELD, F.R.S. A very serviceable manual for preparation work and reference. It has been written especially for medical and pharmaceutical students, and contains at fair length of both inorganic and organic chemistry and contains useful data on the analysis and examination of drugs and morbid products—as, for example, the urine, and blood. Fifteenth edition. 1893. 15*s.* Gurney and Jackson.

Organic Chemistry. By IRA REMSEN. A clear account of the principles, including also the preparation of certain organic substances. 6*s.* 6*d.* Macmillan and Co.

Notes on Analytical Chemistry for Students of Medicine. By A. J. BERNAYS. This is an excellent laboratory book for medical students preparing for every examination, and contains also data of service to the practitioner, for example, the methods of examination of urinary deposits, the estimation of sugar, and the detection of bile constituents &c. in urine. Third edition. 1889. 4*s.* 6*d.* London: J. & A. Churchill.

Practical Organic Chemistry. By S. RIDEAL, D.Sc. A very handy little book for use in the laboratory. It covers all the ground of the London synopsis. 2*s.* 6*d.* H. K. Lewis.

Digitized by Google

of Chemical Physiology and Pathology, by D. HALLIBURTON, M.D., F.R.S. &c. all students. Profusely illustrated. Cr. 8 n: Longmans, Green, and Co. 1891.

ical Basis of the Animal Body. By A. , F.R.S. A first-rate treatise, outcr o Foster's Physiology. Smaller, less ex xpensive than either of the foregoi lete references to original papers. 7s. 6d. London: Macmillan and Co. 1

HISTOLOGY AND EMBRYOLOGY.

hysiological text-books deal with h lly for the pass examinations of t such books are Foster, Landois, as f pecial treatises are:—

ments of Embryology. By Profes F.R.S., and the late Professor Pra econd edition, revised. pp. 470. 188 the best book for those examinat work and manual skill in the subject

al Physiology. By Professors Mic nd J. N. LANGLEY, F.R.S. Fifth ed llently selected series of laboratory uctions to the student. Both, Lond

es of Practical Physiology. By Profe G., D.Sc. Third edition. 1895. Th ly rewritten, with additional illustra l and experimental physiology a medicine; histology not neglec book on the subject; full illustrated.—*Outlines of Phys* edition. 1892. Companion vo ally good; copiously illustrate Griffin and Co.

CHEMISTRY AND PHYSICS.

istry: General, Medical, and Pha TTFIELD, F.R.S. A very service aration work and reference. It l y for medical and pharmaceutical length of both inorganic and o tains useful data on the analysis s and morbid products—as, for d blood. Fifteenth edition. 1892. and Jackson.

ic Chemistry. By IRA REMSEN. inciples, including also the prepa nbstances. 6s. 6d. Macmillan and

on Analytical Chemistry for Stud . BERNAYS. This is an excellent cal students preparing for every also data of service to the practi the methods of examination of u uation of sugar, and the detection &c. in urine. Third edition. 18 London: J. & A. Churchill.

al Organic Chemistry. By S. Ru ly little book for use in the labora round of the London syllabus. It is ris.

Elementary Lessons in Electricity and Magnetism. By SYLVANUS THOMPSON, D.Sc. A standard text-book on the subject. 4s. 6d. Macmillan and Co.

MATERIA MEDICA AND THERAPEUTICS.

Text-book of Pharmacology, Therapeutics, and Materia Medica. By T. LAUDER BRUNTON, M.D., D.Sc., F.R.S. Third edition, containing the additions (1891) to the British Pharmacopœia. 8vo, 21s.; in two vols., 22s. 6d. Supplement separately, 1s. The student for the higher examinations would be well advised to provide himself with this work. It is equally useful as a practical treatise and as a work of reference, and is admirably written. It is not intended for pass examinations or junior students.

A Handbook of Therapeutics. By SIDNEY RINGER, M.D., F.R.C.P., F.R.S. This is another large and important work, designed more for reference than for daily use. Twelfth edition. pp. 632. 1888. 15s. London: H. K. Lewis.

Materia Medica. By HALE WHITE, M.D., F.R.C.P. London: J. & A. Churchill. 7s. 6d. *The Handbook of Pharmacology, Materia Medica, and Therapeutics.* By J. MITCHELL BRUCE, M.D., F.R.C.P. Twenty-eighth thousand. pp. 582. London: Cassell and Co. 1894. Two excellent practical books for students engaged in any of the pass examinations.

Essentials of Materia Medica and Therapeutics. By Sir A. B. GARROD, M.D., F.R.S., &c. Thirteenth edition. 1890. Edited by NESTOR TIRARD, M.D., F.R.C.P. The subject is regarded entirely from a practical therapeutic point of view, and the work, though more useful to the practitioner, can still be used as a book of reference by the student. 12s. 6d. London: Longmans, Green, and Co.

Of other text-books likely to be of value we might mention:—*Materia Medica and Therapeutics: Inorganic Substances.* By C. D. F. PHILLIPS, M.D. Second edition. 1894. pp. 898. 21s. London: J. & A. Churchill.—*Guide to Therapeutics.* By R. FARQUHARSON, M.D., F.R.C.P., &c. Fifth edition. pp. 417. 7s. 6d. London: Smith, Elder, and Co. 1891.—*Materia Medica and Therapeutics.* By Dr. BARTHOLOW. Eighth edition. pp. 820. 21s. London: H. K. Lewis. 1893.—*The Dictionary of Treatment.* By WM. WHITLA, M.D. Q.U.I. American edition. pp. 921. 17s. 6d. London: Henry Renshaw. 1894. A capital, practical book, and pleasant reading.—*Theory and Practice of Medicine.* By F. T. ROBERTS, M.D., F.R.C.P. Ninth edition. 1894. pp. 1059. 21s. London: H. K. Lewis.—*Materia Medica and Pharmacy.* By Dr. GRIFFITHS, Ph.D. Third edition. pp. 464. 7s. 6d. London: Baillière, Tindall, and Cox. 1887.—*Notebook of Materia Medica.* By SOORERBY JACKSON. New edition. Edited by RALPH STOCKMAN, M.D., and J. RUTHERFORD HILL. London: J. Thin.

MEDICINE.

The number of text-books on Medicine is so large, and their general excellence so high, that it is impossible to make a selection with which no one could find legitimate fault. It must always appear that some books as good or better than the specified list have been omitted. We do not for a moment pretend that this is the best possible list, but the student who is guided by these books will be in very good hands.

In systematic medicine the book which for depth a thoroughness occupies the foremost place is the work the "Principles and Practice of Medicine," by the l Dr. HILTON FAGGE and Dr. PYE-SMITH. It is a book wh must be studied by all who are preparing for the hig qualifications, and its unconventional and practical st makes it an easy work to remember. In QUAIN'S D tionary, an admirable collection of monographs, will found articles which may be required to supplement reading of Fagge's Principles; and the same may be s of the System of Medicine, edited by Sir J. RUSSE REYNOLDS, which contains contributions of perennial va from master hands. It is so many years since this syst appeared that a new edition of it would now mean to intents and purposes a new book; but there are articles REYNOLDS' "System" which cannot be overlooked. As l extensive in range, and therefore more useful to the gene student, may be classed the works of Drs. OSLER, BRISTOW ROBERTS, and F. TAYLOR. Of these well-known text-boo those of Professor F. T. ROBERTS and the late BRISTOWE have enjoyed a term of popularity of m than twenty years, each having in that period pas through several editions. Although similar in scope a purpose, there is a strong contrast between these two wor That by Professor ROBERTS is emphatically written for t class-room; its style is restrained and its plan sever systematic. Abounding in information it presents the fa of medicine in a categorical manner, and needs to be closely studied as a mathematical treatise. Many a stud has passed the highest examinations by confining himself its pages; but on the other hand its very merits a characteristics are distasteful to others who seek gre freedom and originality. To them the work of Dr. BRISTO will be more attractive, for here we have almost the an thesis of style and method to that presented in the fi named work. At the same time no sounder guide in t intricate paths of diagnosis and pathology can be found th the highly esteemed physician whose loss we are now depl ing. His work lives after him and will, we venture think, long remain as a standard text-book for students medicine. Meanwhile more recent candidates for favo have appeared, notably the text-books of Dr. W. OSLER Baltimore and Dr. F. TAYLOR of Guy's Hospital. Both a works of a high class, and are admirably suited to th purpose; and already the latter has gained considera favour. On a line with these may be placed the well-arrang Dictionary of Medicine edited by Dr. J. K. FOWLER. It wou not only be invidious but useless to draw distinctions of me here. Lastly, books of smaller scope, but accurate and tru worthy within their limits, are those of Dr. CARTER and I CHARTERIS. To the beginner in medical study these boo may be read in connexion with lectures on the subje but the student must not be content with them for co plete knowledge. Their authors have not designed to iss comprehensive treatises.

Besides the foregoing systematic treatises there is a la and increasing number of books on clinical medicine—so dealing with the whole subject of diagnosis, others w separate portions of this wide subject. Amongst the for may be recommended the work recently published by JUDSON BURY, the manual edited by Dr. FINLAYSON,

Digitized by Google

smaller work of Drs. GIBSON and RUSSELL, or the favourite of many generations of students, and pioneer in this class of literature, Dr. FENWICK'S "Guide." Upon Auscultation there is no better guide than Dr. GEE'S work; whilst upon Urinary Examination, &c., there are many compendia of varied range and style, any one of which may be put to good use by the clinical clerk. We cannot attempt to single out by name the various useful monographs that are at the student's disposal; he will be well advised to follow the fashion of his school in this matter.

Text-book of the Principles and Practice of Medicine. By the late HILTON FAGGE, M.D., F.R.S., and P. H. PYE-SMITH, M.D., F.R.C.P., F.R.S. Third edition. 1891. pp. 2209. 40*s*. London: J. & A. Churchill.

The Theory and Practice of Medicine. By J. S. BRISTOWE, M.D., F.K.S. Seventh edition. 1890. pp. 1285. 21*s*. London: Smith, Elder, and Co.

The Principles and Practice of Medicine. By W. OSLER, M.D. 1892. pp. 1080. 24*s*. London: Young J. Pentland.

Text-book of Medicine. By Professor STRÜMPELL. Second edition. 1893. pp. 1043. 28*s*. London: H. K. Lewis.

Handbook of the Theory and Practice of Medicine. By F. T. ROBERTS, M.D., F.R.C.P. Ninth edition. 1894. pp. 1059. 24*s*. London: H. K. Lewis.

Manual of the Practice of Medicine. By F. TAYLOR, M.D., F.R.C.P. Third edition, with Twenty-five Engravings. 1893. pp. 932. 15*s*. London: J. & A. Churchill.

Elements of Practical Medicine. By A. H. CARTER, M.D. F.R.C.P. Seventh edition. 1895. pp. 496. 10*s*. London; H. K. Lewis.

Guide to Practice of Medicine. By M. CHARTERIS, M.D., L.R.C.S. Edin., &c. Seventh edition. With engravings. 1894. pp. 712. 10*s*. London: J. & A. Churchill.

Dictionary of Medicine. Edited by RICHARD QUAIN, Bart., M.D. Lond., LL.D. Edin., F.R.S., assisted by F. T. ROBERTS, M.D., F.R.C.P., and J. MITCHELL BRUCE, M.D., F.R.C.P. Two vols. 1894. 40*s*. nett. London: Longmans, Green, and Co.

An Index of Diseases: Their Diagnosis, Symptoms, and Treatment. By THOMAS HAWKES TANNER, M.D. Fourth edition. Revised by PERCY BOULTON, M.D. 10*s*. 6*d*. London: Henry Renshaw.

Dictionary of Practical Medicine. Edited by J. K. FOWLER, M.D., F.R.C.P. 1890. pp. 942. 21*s*. London: J. & A. Churchill.

A Manual of Diseases of the Nervous System. By W. R. GOWERS, F.R.S. Vol. I. Diseases of the Nerves and Spinal Cord. Second edition, roy. 8vo, with 179 engravings, 15*s*. 1891. Vol. II. Diseases of the Brain and Cranial Nerves; General and Functional Diseases of the Nervous System. Second edition, roy. 8vo, with 182 engravings, 20*s*. 1893.

The Nervous System, Diseases of. By J. A. ORMEROD, M.D., F.R.C.P., Physician to the National Hospital for the Paralysed and Epileptic. With 66 illustrations, fcap. 8vo, 8*s*. 6*d*. 1892. Two useful works on the subject on which they treat, published by J. & A. Churchill.

Clinical Diagnosis. By JUDSON BURY, M.D., M.R.C.S. London: Charles Griffin and Co.—A very admirable and clearly written work.

Clinical Manual. By JAMES FINLAYSON, M.D., F.F.P.S. Glasg. Third edition. 1891. pp. 719. 8*s*. 6*d*. London: Smith, Elder, and Co.

Manual of Medical Diagnosis. By Professor H. VIERORDT. Large 8vo. With 178 Engravings, many in colour. 1892. pp. 700. 18*s*. Edinburgh and London: Young J. Pentland.

Medical Diagnosis: A Manual of Clinical Methods. By J. J. GRAHAM BROWN, M.D., F.R.C.P., F.R.S. Edin. Third edition. Crown 8vo, cloth. 1887. pp. 380. 10*s*. 6*d*. Edinburgh: Bell and Bradfute.

Fenwick's Students' Guide to Medical Diagnosis. Edited by BRADFORD FENWICK, M.D. Seventh edition. With 117 engravings. 1891. pp. 352. 7*s*. London: J. & A. Churchill.

Physical Diagnosis: A Guide to Methods of Clinical Investigation. By G. A. GIBSON, M.D., F.R.C.P. Edin., and Sir WILLIAM RUSSELL, M.D., F.R.C.P. Edin. Second edition. With 109 illustrations, many coloured. 1893. pp. 383. 10*s*. 6*d*. Edinburgh and London: Young J. Pentland.

Auscultation and Percussion. By SAMUEL J. GEE, M.D., F.R.C.P. Fourth edition. 1893. pp. 327. 6*s*. London: Smith, Elder and Co.

Cardiac Outlines. By WILLIAM EWART, M.D., F.R.C.P. With 62 illustrations. 1892. pp. 165. 5*s*. 6*d*. London: Baillière, Tindall, and Cox.

Clinical Diagnosis. By Professor R. VON JAKSCH. Second edition. Translated and edited by JAMES CAGNEY, M.D., M.R.C.P. 25*s*. London: Charles Griffin and Co.

Guide to Examination of Urine. By J. WICKHAM LEGG. M.D., F.R.C.P. Seventh edition. 1893. pp. 136. 3*s*. 6*d*. London: H. K. Lewis.

Notes on Examination of Blood and Excreta. By SIDNEY COUPLAND, M.D., F.R.C.P. Third edition. 1892. pp. 64 1*s*. 6*d*. London: H. K. Lewis.

SURGERY.

Of surgical almost the same remarks can be made as thos we have made upon medical works. The last edition Holmes' and Hulke's treatise was published in 1883. Th will be found useful for reference by candidates for t higher examinations, as many of the monographs are exc lent and authoritative. In the same way *Heath's Dictiona of Practical Surgery* is chiefly of use as a first-class work reference. *Erichsen's Science and Art of Surgery*, the te edition of which appeared a few weeks ago, remains the b text-book which we have on the subject from the stude point of view. Clear and comprehensive, it is a model what a text-book should be, the illustrations are excell and the type good.

The use of *Keetley's Index of Surgery* as a book ou which to revise general knowledge immediately previo an examination is well known. The students, to benef the work, must be acquainted with the contents of the text-books, and only require to refresh the memor salient points. The chapter on Antiseptics is espe valuable, gaining point from the style adopted in writi Of several books on Surgical Diagnosis those by I and Pearce Gould may be read with advantage t student. The same may be said for the works on Ope Surgery by Treves and by Jacobson. *Jacobson's tions of Surgery* is an admirable text-book. The infor

Digitized by Google

is not confined to the mere description of operations, but includes reasons for their performance. The smaller books of Treves and Barker are volumes of convenient size, which contain all that is necessary for the ordinary pass examinations. *Holmes's Treatise on Surgery* is the great rival to Erichsen's in the student's favour. It is not quite so exhaustive in several directions, but its clear and forcible manner will always insure it a wide audience, and the student who knows his Holmes will come to no harm. *Druitt's Surgeon's Vade-Mecum* is of somewhat similar proportions to the last-named, and is intended to answer the same purpose. *Walsham's Theory and Practice of Surgery* is a handy volume which has obtained great success as a student's handbook. It has recently been revised and a new edition brought out, so that the reader will not find himself behind the times.

A System of Surgery. Edited by TIMOTHY HOLMES F.R.C.S., and J. W. HULKE, F.R.C.S., F.R.S. Third edition. Three vols. With Coloured Plates and numerous Illustrations. Price £4 4s. London: Longmans, Green, and Co.

The Science and Art of Surgery. By Sir J. E. ERICHSEN, F.R.S., LL.D. Ninth edition. Edited by the late MARCUS BECK, M.S., F.R.C.S. 1888. With 1025 Wood Engravings. Two vols. 48s. London: Longmans, Green, and Co.

A System of Surgery. Edited by FREDERICK TREVES, F.R.C.S. 1895. Vol. I. With two Coloured Plates and 463 Illustrations. London: Cassell and Co.

This is a notable addition to our standard works on Surgery. It is thoroughly reliable text-book, well printed, copiously illustrated, accurate, and fully abreast of current knowledge. Only the first volume has been issued, but the second volume promises to be as excellent as the first.

Dictionary of Practical Surgery. By C. HEATH, F.R.C.S. Third edition. 1889. Two vols. Vol. I., pp. 970; Vol. II., pp. 884. 32s. London: Smith, Elder, and Co.

Surgery. By C. W. MANSELL MOULLIN, F.R.S. 1891. With 497 Engravings. pp. 1413. 34s. London: J. & A. Churchill.

Treatise on Surgery. By T. HOLMES, F.R.C.S., &c. Fifth edition. 1888. pp. 1004. 30s. London: Smith, Elder, and Co.

Manual of Practice of Surgery. By T. BRYANT, M.D., F.R.C.S. Fourth edition. 1884. With 750 Engravings. pp. 1520. 32s. London: J. & A. Churchill.

Manual of Surgery. By F. TREVES, F.R.C.S. 1894. pp. 574. London: Cassell and Co.

Druitt's Surgeon's Vade-Mecum. Edited by STANLEY BOYD, F.R.C.S. Twelfth edition. With 373 Engravings. pp. 1000. 16s. London: J. & A. Churchill.

Index of Surgery. By C. R. B. KEETLEY, F.R.C.S., &c. Fourth edition. 1887. pp. 526. 10s. 6d. London: Smith, Elder, and Co.

Surgery: its Theory and Practice. By W. J. WALSHAM, F.R.C.S., &c. Fifth edition. 1895. With 380 Engravings. pp. 766. 12s. 6d. London: J. & A. Churchill.

Operative Surgery. By F. TREVES, F.R.C.S. 1894. pp. 1550. London: Cassell and Co.

Surgical Operations. By A. E. J. BARKER, F.R.C.S. With 91 Wood Engravings. 12s. 6d. London: Longmans, Green, and Co.

The Science and Practice of Surgery: a Complete Text-book. By F. J. GANT, F.R.C.S., Senior Surgeon, Royal Free Hospital. Third edition, about 1100 engravings, 2 vols. Price 36s.

The Operations of Surgery. By W. H. A. JACOBSON, F.R.C.S. Third edition, nearly ready. London: J. & A. Churchill.

Guide to Surgical Diagnosis. By C. HEATH, F.R.C.S. Second edition. 1888. pp. 240. 6s. 6d. London: J. & A. Churchill.

Surgical Diagnosis. By A. P. GOULD, F.R.C.S. &c. pp. 584. London: Cassell and Co.

Minor Surgery and Bandaging. By C. HEATH, F.R.C.S. Tenth edition. 1894. With 158 Engravings. pp. 389. 6s.

Essentials of Bandaging. By the late BERKELEY HILL, F.R.C.S. Sixth edition. 1889. pp. 365. 5s. London: H. K. Lewis.

MIDWIFERY.

In this subject the student will find it advantageous to have two books: one a small and elementary work, which he can, if he likes, take with him when attending his cases; and the other, a larger text-book, for systematic reading.

Of the elementary books we mention three;—

First Lines of Midwifery. By G. ERNEST HERMAN, M.B., F.R.C.P. 1892. London: Cassell and Co.—*Obstetric Aphorisms for Students.* By J. G. SWAYNE, M.D. Tenth edition. Fcap. 8vo, with twenty engravings. 3s. 6d. 1893. London; J. & A. Churchill.—*An Introduction to Midwifery.* By ARCHIBALD DONALD, M.D.—All three are excellent for their purpose—that is, they serve well to instruct the student as to his practical duties and the points to be noted and watched in attending his first cases of labour. Dr. Swayne's book is the old-established favourite. The other two are more modern, but by any of the three the student will find himself much fortified.

General Text-books:—

A Manual of Midwifery. By A. L. GALABIN, M.D., F.R.C.P.—A very deservedly popular book; literally a manual as it is in one volume; clear and precise and sufficiently informatory to provide the student with all the information necessary for pass examinations. Third edition. With 262 engravings. 15s. London; J. & A. Churchill.

The Science and Art of Midwifery. By W. T. LUSK, M.D.—This American work is undoubtedly in many ways the best English text-book on the subject. The amount of information contained is very large, the references complete, and the plan of the book is easy to follow. For honour examinations this book is a necessity. Fourth edition. 1892. pp. 671. 16s. London: H. K. Lewis.

The Science and Practice of Midwifery. By W. S. PLAYFAIR, M.D., F.R.C.P. Eighth edition. Two volumes, each containing 430 and 443 pages respectively.—This has long been a deservedly popular work with students. It practically held the field till the appearance of the two previous treatises, and is still, and we think fitly, the most widely read text-book on the subject. The work is written in such a simple, easy style that the student may find a difficulty in remembering what he has read. Two volumes. Eighth edition. 1893. 28s. London: Smith, Elder, and Co.

Digitized by Google

The student will also find the following books of reference of use:—

Text-book of Midwifery. By the late OTTO SPIEGELBERG. Translated from the second German edition by Dr. HURRY. This work in two volumes is published by the New Sydenham Society. Although a text-book in name it is not well adapted to the immediate needs of the student, who, however, may be advised to consult it on special points.—*Difficult Labour*, by G. ERNEST HERMAN, M.B., F.R.C.P., will also be found a useful work of reference on its subject.

GYNÆCOLOGY.

A Manual of Gynæcology. By BERRY HART, M.D., and FREELAND BARBOUR, M.D.—The work consists of two parts and an appendix. Part I. deals with the Anatomy, Physiology, and Methods of Examination of the Female Pelvic Organs, and Part II. with the diseases peculiar to the organs. This favourite manual is especially strong in its anatomical and purely scientific sections, if somewhat less complete as a clinical guide. It has the advantage of giving at the end an Index of Recent Gynæcological Literature. Fourth edition. pp. 722. Illustrated with lithographs and 400 woodcuts. London: W. and A. K. Johnston.

The Student's Guide to the Diseases of Women. By A. L. GALABIN, M.D., F.R.C.P.—A small book that has been useful to several generations of students, and will be useful to generations more. Fifth edition. 1893. pp. 507. 8*s.* 6*d.* London: J. & A. Churchill.

A Practical Text-book of the Diseases of Women. By ARTHUR H. N. LEWERS, M.D.—This is also a small book, but somewhat larger than the above, and treats the subject rather more from the clinical point of view. Fourth edition. 1893. pp. 439. 10*s.* 6*d.* London: H. K. Lewis.

The Diseases of Women and their Treatment. By H. MACNAUGHTON JONES, M.D., F.R.C.S.I., F.R.C.S.E. Sixth edition. Price 12*s.* 6*d.* London: Baillière, Tindall, and Cox.—This is a well-known work.

The following books of reference are recommended:—*Clinical Gynæcology.* By T. MOORE MADDEN, M.D.—This book consists of forty-seven lectures on the diseases of women, and may be usefully consulted on special points.—*A Treatise on Gynæcology.* By S. POZZI, M.D.—This work, in three volumes, is published by the New Sydenham Society, and, while not well adapted for general reading, will be found invaluable for reference. The same, to a greater or less extent, applies to the following books:—*Diseases of the Ovaries.* By LAWSON TAIT, F.R.C.S. Fourth edition. 1883.—*Abdominal Surgery.* By J. GREIG SMITH. Third edition. 1889.—*The Surgical Diseases of the Ovaries and Fallopian Tubes.* By J. BLAND SUTTON, F.R.C.S.—*The Diagnosis and Surgical Treatment of Abdominal Tumours.* By Sir SPENCER WELLS.—*Clinical Lectures on the Diseases of Women.* By J. MATTHEWS DUNCAN, M.D. Fourth edition. 1890.

DISEASES OF CHILDREN.

It is only natural that students should be obliged by the medical schools to give some attention to the study of the diseases of children, when it is considered that in general practice one patient at least out of every three will be a child. At present some of the examining boards, as the Royal University of Ireland, require candidates for the M.B. degree to produce certificates of having attended a practical course on the diseases of children, and the studen are also specially examined in this subject. We therefc suggest for their guidance the following text-books: *Diseases of Children, Medical and Surgical.* By HEN ASHBY, M.D., F.R.C.P., and G. A. WRIGHT, B.A., M. F.R.C.S. Eng. Enlarged and improved edition, with 178 ill trations. 8vo. pp. 248. London: Longmans, Green, and This admirable work, as it deals with diseases of chil from both a medical and surgical point of view, can recommended to students as containing everything that t will require to know.—*The Diseases of Children.* By JA F. GOODHART, M.D., F.R.C.P. Fifth edition. pp. 1894. 10*s.* 6*d.* London: J. & A. Churchill. For t who want to study diseases of children from a me aspect we can recommend this most popular manual, wri as it is, by one who convinces the reader that he has everything he describes.—*The Diseases of Chil (Medical).* By H. BRYAN DONKIN, M.D., F.R.C.P. Me 8vo. 16*s.* London: Charles Griffin and Co. This many respects a most original book. For those stu who desire to know the surgical aspect of affections of children there are two useful books, *Surgical Diseases of Children*, by E. OWEN, F.R.C.S. Eng., price 9*s.*, Cassell and Co., Limited, L Paris, and New York; and *The Surgical Diseases of Cl and their Treatment by Modern Methods*, by D'ARCY P M.A., M.B. Oxon., F.R.C.S. Eng., crown 8vo, price 1 London: H. K. Lewis.—A manual which is used a go by Edinburgh students is *Disease in Children*, by CARMICHAEL, M.D., F.R.C.P. Ed. Crown 8vo. p Price 10*s.* 6*d.* Young J. Pentland: Edinburgh and Lor The following larger works are recommended for ref EUSTACE SMITH'S *Treatise on Disease in Children.* edition. Price 22*s.* pp. 895. London: J. & A. Chur *Diseases of Children* (Medical and Surgical). Ed KEATING. Eight vols. 12*s.* 6*d.* per volume. Edinbu London: Pentland.—*Lectures on Children's Disea* HENOCH. Two vols. Translated by JOHN THOMPSO F.R.C.P. Ed., from the fourth German edition. This is published by the New Sydenham Society.—*Di Children.* Edited by LOUIS STARR, M.D., and si ciates. Imperial 8vo volume. Price 40*s.* London: This is the most recent large work on diseases of compiled in America. It is well got up and profu trated.—Another very useful book is that of Dr. C *On the Principles and Exact Conditions to be Obser Artificial Feeding of Infants.* London: Smith, E Co. Price 5*s.*

OPHTHALMOLOGY.

Either of the two following handbooks on Opht will be found to contain all that is necessary to t of medicine who has no inclination to make a sp of the subject.

Handbook of Diseases of the Eye. By HENRY I M.B., F.R.C.S.I. Edited by Louis Werner, M edition. pp. 582. 1895. Price 10*s.* 6*d.*, by H. 136, Gower-street.

The Diseases of the Eye. By EDWARD N F.R.C.S. Fifth edition. 1890. Student's Gu Price 7*s.* 6*d.*, by J. & A. Churchill, 11, New street.

Digitized by Google

By those who wish for fuller information on the subject the larger text-books must be consulted, of which, perhaps, *The Text-book of Ophthalmology*, by Professor FUCHS, of the Vienna University, is the most generally useful. This has been recently translated from the German into English by A. Duane, and is published in one large octavo volume, with 173 illustrations, price 21s., by H. K. Lewis, 136, Gower-street.

Most students find the study of errors of refraction difficult and unattractive, and are consequently inclined to neglect this important branch of the subject. "The Manual for Students on the Refraction of the Eye," by GUSTAVUS HARTRIDGE, is a most useful little book, as it explains simply the principles on which are based the methods in use in the out-patient department.

It is unnecessary, and, indeed, undesirable, here to enumerate all the valuable text-books which have been written on diseases of the eye, but the following may be mentioned as generally useful books:—

Diseases of the Eye. By GEORGE BERRY, M.B., F.R.C.S. Edin. Edinburgh and London: Young J. Pentland.

Handbook of Ophthalmic Science and Practice. By HENRY JULER, F.R.C.S.

Diseases of the Eye. By HENRY D. NOYES, A.M., M.D. London: H. K. Lewis.

To those who are conversant with the French language the "Traité Complet d'Ophthalmologie," by L. DE WECKER and E. LANDOLT, may be recommended as the most valuable work of reference. It is published in four large volumes at a price of about 20 francs each volume, and is consequently scarcely adapted for the student's use. A German edition of this work may also be obtained.

Diseases of the Eye. By EDWARD NETTLESHIP, F.R.C.S., Ophthalmic Surgeon to St. Thomas's Hospital. Fifth edition. Fcap. 8vo, with 164 engravings and a coloured plate illustrating colour-blindness, 7s. 6d. 1890. London: J. & A. Churchill.

PATHOLOGY.

Manual of General Pathology. By JOSEPH FRANK PAYNE, M.D. Oxon., F.R.C.P. pp. 702. Illustrations 156. Deals specially with general pathology and pathological anatomy, and the processes and causes of disease, including parasites, both animal and vegetable. Special pathology and pathological histology are not touched upon, but on general pathology it is one of the best books in the language. London: Smith, Elder, and Co. 1886.

A Text-Book of Pathology, Systematic and Practical. By Professor D. J. HAMILTON. An admirably original, but somewhat unequal work. The most complete and systematic work published in the English language. Contains a very full and accurate bibliography. Invaluable for reference and for study for the higher examinations. Published in two volumes (the second volume is divided into two parts), which may be bought separately. Vol. I. (London: Macmillan and Co., 1889, pp. 736, 295 illustrations, woodcuts and coloured lithographs, price 21s. net) deals with the technique of the post-mortem room and the histological and bacteriological laboratories. An account is also given of the general pathological processes of the diseases of the blood, the heart and bloodvessels, and of tumours. Vol. II., 1895, Part 1 (172 illustrations, pp. 514, price 15s. net) treats of diseases of the air passages and lungs, of liver, of the genito-urinary apparatus, and the alimentary tract, except the intestines, whilst Part 2 of Vol. II. (225 illustrations, pp. 624, price 15s. net) completes the description of the diseases of the alimentary tract and then takes in turn the nervous system (very good), diseases of mamma, bones and joints, the skin, malformations, diseases of the fœtal membranes and placenta, vegetable and animal parasites, animal heat and fever. London: Macmillan and Co.

A Text-book of Pathological Anatomy and Pathogenesis. By Professor ERNST ZIEGLER. Translated and edited for English students by DONALD MACALISTER, M.D., F.R.C.P. A good text-book for the higher examinations; like Professor HAMILTON'S work, somewhat unequal in the treatment of different subjects; the English edition is now not quite up to date, having appeared in 1886. References to literature very full. The three parts can be bought separately. Part I. 1885, pp. 360, 117 figs.: General Pathological Anatomy, treating of malformations, anomalies in the distribution of blood and lymph, disturbances of nutrition, inflammation, &c., tumours (very good), and parasites. Part II., 1887, pp. 371, 83 figs.: Blood and lymph, the vascular mechanism, the spleen and lymphatic glands, the serous and mucous membranes, the skin, the alimentary tract, and liver and pancreas. Part III., 1886, pp. 391, 89 figs.: The urinary and respiratory organs and the central and peripheral nervous systems. Each part, 12s. 6d. London: Macmillan and Co. A German edition in two volumes published by Gustav Fischer.

Practical Pathology. By GERMAN SIMS WOODHEAD, M.D., F.R.S.E. Third edition. 1892. pp. 652. With 195 Coloured Plates from Original Drawings.—This book is almost essential to the proper study of the subject. It is not only thoroughly clear and well arranged, but beautifully illustrated. The points where the student might be expected to be most in difficulty have received special attention. Edinburgh and London: Young J. Pentland.

An Introduction to Pathology and General Morbid Anatomy. By T. HENRY GREEN, M.D., F.R.C.P. Revised and enlarged by H. MONTAGUE MURRAY, M.D., F.R.C.P. Engravings.—An excellent *résumé* of pathology from students' point of view. Brought well up to date, especially in the sections dealing with inflammation, the specific infectious fevers, and the nervous system. May be confidently recommended as giving a very good and accurate account of the groundwork of pathology and as containing sufficient information to enable the student to pass an ordinary examination on the subject. Price 12s. 6d. London: Henry Renshaw.

A Text-book of Morbid Histology for Students and Practitioners. By ROBERT BOYCE, M.B., M.R.C.S. pp. 400, with 130 Coloured Photographic Illustrations. 31s. London: H. K. Lewis. 1892.—Contains good descriptions of morbid histological specimens; also a number of photographs, which, however, are of very unequal merit and value. Exceedingly useful for the advanced student and laboratory worker. A carefully selected bibliography appended.

The following books are hardly to be used as text-books

but for one reason or another the student will do well to supplement his reading by consulting them:—

Lectures on Surgical Pathology. By Sir JAMES PAGET, Bart., F.R.S., &c. Revised and edited by Professor WM. TURNER, F.R.S. pp. 844. Illustrations 130. London: Longmans, Green, and Co. 1876. Fourth edition.—Still one of the most valuable books of reference on surgical pathology in our language, and should be read by every student as a model on which to base methods of observation and study.

An Introduction to General Pathology. By JOHN BLAND SUTTON, F.R.C.S. pp. 390. London: J. & A. Churchill. 1876.—An admirable introduction to the subject of evolution in pathology, well worth study by those who wish to gain more than a mere examination knowledge of the subject.

Lectures on Pathological Anatomy. By SAMUEL WILKS, M.D., F.R.S., and the late WALTER MOXON, M.D., F.R.C.P. Third edition, thoroughly revised by SAMUEL WILKS, M.D., LL.D., F.R.S. London and New York: Longmans, Green, and Co. 1889.—An admirable description of macroscopic morbid anatomy, doing for medicine what Paget's lectures have done for surgery. May be studied with advantage both before and after practical work is engaged in.

Lectures on Pathology. By the late HENRY GAWEN SUTTON, M.B., F.R.C.P. Edited by MORRIS EDEN PAUL, M.D.; and Revised by SAMUEL WILKS, M.D., LL.D., F.R.S. London: J. & A. Churchill. 1891.—An admirable, philosophical, and original work on medical pathology, especially useful for senior and qualified students of medicine.

A Manual of Pathology. By JOSEPH COATS, M.D. pp. 977. Illustrations 364. London: Longmans, Green, and Co. Second edition. 1889.—An interesting treatise on pathology; covers a great deal of ground; in most cases very reliable, and a good text-book, especially for the student preparing for the higher examinations.

The following books have different uses for students, which we have tried to briefly indicate:—

Practical Pathology. By JOHN LINDSAY STEVEN, M.D. pp. 266. Glasgow: James Maclehose and Sons. 1887.—A concise and well-arranged description of methods and of pathological anatomy and histology. There are no illustrations, but the descriptions are clear and concise. Useful for a student going in for examination or as a supplement to demonstrations.

Practical Pathology and Morbid Histology. By HENEAGE GIBBES, M.D. pp. 320. Illustrated with 60 Photographic Reproductions. Edinburgh and London: Young J. Pentland. 1891.—A good practical book with a series of photographs of typical pathological microscopic specimens. Useful for private laboratory work rather than for examination purposes.

Elements of Surgical Pathology. By AUGUSTUS J. PEPPER, M.S., M.B. Lond., F.R.C.S. Eng. pp. 532. 84 Engravings. London, Paris, and New York: Cassell and Co., Limited. Fourth edition. 1894.—A compact little handbook of surgical pathology.

A Handbook of Surgical Pathology. By W. J. WALSHAM, M.B., F.R.C.S. Eng.; and D'ARCY POWER, M.A., M.B. Oxon., F.R.C.S. Eng. pp. 634. London: Baillière, Tindall, and Cox. Second edition. 1890.—A clear and concise description of the specimens in the Museum of St. Bartholomew's Hospital, and therefore specially useful to students of that school or to those who have access to that museum. But the descriptions are so good that this work will serve as a capital text-book to any student preparing for an examination in surgical pathology.

Pathological Anatomy of Diseases. By NORMAN MOORE, M.D. London: J. & A. Churchill. 1889.—A small, accurate, and concise, but not very full, student's manual of morbid anatomy of 416 pp., with 110 figures.

Practical Morbid Anatomy. By H. D. ROLLESTON, M.A., M.D., F.R.C.P.; and A. A. KANTHACK, M.D., M.R.C.P. Cambridge University Press. 1894. pp. 240.—A capital account of the methods and course of procedure to be adopted in the post-mortem room. Practical, but thoroughly scientific throughout.

Section Cutting and Staining. By WALTER S. COLMAN M.B. Lond. London: H. K. Lewis. 1888. pp. 107.—A handy little guide to the preparation of normal and morbid histological specimens. Concise, and gives everything that is really necessary for ordinary class work.

BACTERIOLOGY.

The following works will be found useful to students either for examination purposes or for special study:—

Ptomaines, Leucomaines, and Bacterial Proteids. By Professor VICTOR C. VAUGHAN, Ph.D., M.D.; and Assistant Professor FREDERICK G. NOVY, Sc.D., M.D. Second edition. pp. 391. Revised and enlarged. Philadelphia: P. Blakiston, Son, and Co. 1891.—The best book in the language on bacterial products and poisons. Well up to date as regards methods. A new edition is in course of preparation.

Elementary Practical Bacteriology, including Bacteriological Analysis and Chemistry. By A. A. KANTHACK, M.R.C.P., and J. H. DRYSDALE, M.B., M.R.C.P. London: Macmillan and Co. 1895. pp. 181. Sixteen woodcuts. Price 4s. 6d.—An admirable guide to the elementary study of bacteriology. The work deals in turn with general and special methods of cultivation and examination of organisms, with the more important species of bacteria, then with bacteriological analysis and bacterial chemistry.

Practical Guide to the Demonstration of Bacteria in Animal Tissues. By Dr. H. KÜHNE. Translated and Edited by VINCENT DORMER HARRIS, M.D., London: Baillière, Tindall, and Cox. 1890. pp. 53; A practical little handbook.

Pathological Mycology. By G. SIMS WOODHEAD and ARTHUR W. HARE, M.D. Section I.: Methods. Edinburgh and London: Young J. Pentland. well-illustrated description of bacteriological containing also a bibliography of the more works. The first text-book on the subject in English, and somewhat out of date, but containing descriptions of the manipulative methods.

Digitized by Google

Bacteriological Technology for Physicians. By Professor C. J. SALOMONSEN. Translated by WILLIAM TRELEASE. pp. 162, with 72 figures in the text. New York: William Wood and Co. 1890.—A most concise and accurate work on methods, well adapted to the use of the student, as the apparatus described as necessary is both simple and inexpensive.

Manual of Bacteriology for Practitioners and Students. With especial reference to Practical Methods. By Professor S. L. SCHENK. Translated by W. R. DAWSON, B.A., M.D. With an Appendix by the Translator. 100 Illustrations, partly coloured. London and New York: Longmans, Green, and Co. 1893.—A really good student's text-book.

Studies on Fermentation. By L. PASTEUR. Translation, with Notes, Index, and original Illustrations, by FRANK FAULKNER and D. CONSTABLE ROBB, B.A. London: Macmillan and Co. 1879. pp. 418, with 12 plates and 85 figures in text.—An admirable work and one that should be read by every advanced student of bacteriology.

On Fermentation. By P. SCHÜTZENBERGER. Fourth edition. London: Kegan Paul, Trench, Trübner, and Co., Ltd. 1891. pp. 331, with 28 Illustrations. (Vol. XX., International Scientific Series.)—A capital *résumé* of the subject for advanced students.

Bacteria and their Products. By GERMAN SIMS WOODHEAD, M.D. 1891. pp. 459, with 20 Photo-micrographs. London: Walter Scott.—Gives a description of the more important micro-organisms and the diseases they produce, and of fermentation; also a short history of bacteriology; includes an appendix dealing with bacteriological methods and with the classification and identification of micro-organisms. Is in every respect a first-class text-book, excellent in arrangement and clear and full in detail.

A Manual of Bacteriology. By GEORGE M. STERNBERG, M.D. New York: William Wood and Co. 1892.—A most complete and exhaustive work of 886 pages, of which over a hundred are devoted to bibliography. An encyclopædic, painstaking, and usually accurate *résumé* of the subject. Well illustrated with chromo-lithographic plates and 268 engravings. Too ponderous for the ordinary student, but very useful for the advanced worker.

Manual of Bacteriology.—By EDGAR M. CROOKSHANK, M.B. London: H. K. Lewis.—A well-written and well-illustrated treatise on the subject. A good text-book, especially for those who have no opportunity of attending a practical course. We are glad to note that a new edition will shortly be issued.

FORENSIC MEDICINE.

Manual of Medical Jurisprudence.—By A. S. TAYLOR. Edited by T. STEVENSON, M.D.—Twelfth edition. 1891. Fifty-six engravings. 14*s.* London: J. & A. Churchill. An authoritative text-book.

Principles of Forensic Medicine.—By W. A. GUY and DAVID FERRIER, M.D., F.R.S. Seventh edition just published. 16*s.* The work has been practically rewritten under the direction of Professor W. R. SMITH, M.D., F.R.S. Edin. London: Henry Renshaw.

Handbook of Forensic Medicine. By A. HUSBAND. Fifth edition. 1889. pp. 623. 10*s.* 6*d.* London: Baillière, Tindall, and Cox.—This is the best of the smaller books on the subject and will be found an excellent supplementary or introductory work to wider reading.

Text-book of Forensic Medicine and Toxicology. By ARTHUR P. LUFF, M.D., B.Sc. Lond. 2 vols. pp. 416 and 360. With numerous illustrations. London and New York: Longmans, Green, and Co.—This recently published work is one of the best on the subject.

Poisons: their Effects and Detection. By ALEXANDER WYNTER BLYTH, M.R.C.S. Third edition. Revised and Enlarged. 1895. 21*s.* London: Chas. Griffin and Co.—A well-known work, much in esteem with Toxicologists, partly as a book of reference, but chiefly as an excellent guide to the detection of poisons. The recent edition treats of the cadaveric alkaloids or ptomaines, and contains also a separate chapter on the connexion existing between the arrangement of the constituent parts of an organic molecule and physiological action.

MEDICAL ELECTRICITY.

Medical Electricity: a Practical Handbook for Students and Practitioners. By H. LEWIS JONES, M.A., M.D., F.R.C.P. Second edition. With illustrations, crown 8vo, 10*s.* 6*d.* London: H. K. Lewis.—This is the best work on the subject in a small compass with which we are acquainted. Of course, it does not pretend to go as fully into the subject as the treatises of Von Ziemssen, and Beard, and Rockwell; but as a thoroughly practical guide to electrical diagnosis, the choice, preservation, and use of electrical apparatus for medical purposes, and the method of application, it is unequalled. The illustrations, reproduced from photographs of patients with paralysis of particular muscles or groups of muscles are a most useful feature of the work.

MISCELLANEOUS.

The following works will prove of service:—

The Anatomy of the Nasal Cavity, and its Accessory Sinuses. By Dr. A. ONODI, Lecturer on Rhino-Laryngology in the University of Budapest. An atlas for practitioners and students, translated by ST. CLAIR THOMSON, M.D. Lond., F.R.C.S. Eng., M.R.C.P. Lond. Plates, small 4to, 6*s.* nett. London: H. K. Lewis.

Diseases of the Ear. Including the Anatomy and Physiology of the Organ, together with the treatment of the affections of the Nose and Pharynx which conduce to Aural Disease (a Treatise). By T. MARK HOVELL, F.R.C.S. Edin., M.R.C.S., Aural Surgeon to the London Hospital and Lecturer on Diseases of the Throat in the College, &c. 8vo, with 122 engravings. 18*s.* 1894. London: J. & A. Churchill.

A System of Dental Surgery. By Sir JOHN TOMES, F.R.S., and C. S. TOMES, M.A., F.R.S. Third edition, crown 8vo, with 292 engravings. 15*s.* 1887. London: J. & A. Churchill.

Dental Anatomy, Human and Comparative. A Manual. By CHARLES S. TOMES, M.A., F.R.S. Fourth edition. Crown 8vo, with 235 engravings. 12*s.* 6*d.* 1894. London: J. & A. Churchill.

Manual of Botany. Vol. I. Anatomy and Morphology.

Digitized by Google

By J. REYNOLDS GREEN, Sc.D., M.A., F.R.S., Professor of Botany to the Pharmaceutical Society. Crown 8vo, with about 778 engravings. 7s. 6d. 1895. London: J. & A. Churchill.

BACTERIOLOGY AND THE MEDICAL CURRICULUM.

WHENEVER the addition of a new subject to the curriculum of a medical student is suggested it is very properly pointed out that the present day medical student has already a sufficient amount of work to do in the time at his disposal, even under the conditions afforded by the five years curriculum. At the same time it must be borne in mind that every advance made in the domain of pure science must be accompanied or followed by corresponding modifications in the practice of medicine and surgery, so that it may be necessary from time to time to reconsider and revise the course of study in order that the student may be trained to apply to the greatest advantage the latest knowledge obtained for the welfare of his patients. Bearing this in mind, and taking into consideration the enormous advances, or, at any rate, the great modifications, that have been suggested for the prevention and treatment of disease as the outcome of bacteriological investigation, it is now almost imperative that those who are engaged in the teaching and study of medicine should consider the position of bacteriology in medical education with regard (*a*) to students proper, and (*b*) to those students of more mature years known as post-graduates.

We think that the time has nearly come when it will be insisted upon that every medical student should receive not only some systematic instruction in the principles of bacteriology, but, more important still, should be put through a thorough, if short, course of practical laboratory instruction, in which the theories propounded in the class-room may be clearly illustrated. It may be asked, What is to be gained by the adoption of such a course? Apart from anything else, surely the precision and accuracy requisite for the successful carrying out of bacteriological experiments afford the best kind of technical and mental training, for the slightest error in manipulation or fault in judgment may render useless weeks of accurate work. Then, again, when a student comes to study surgery, especially the treatment of wounds, operative or accidental, he will find that he knows more concerning the true principles of antiseptic treatment if he has enjoyed a week's work in a bacteriological laboratory than he can pick up in six months' ward work, even under the most skilled and experienced teachers. There are so many points to be mastered concerning the actual operation or the nature of the wound, so many side issues to draw off the attention from the main principle, so much mechanical work to do in connexion with the actual dressing, that the fundamental principle on which so much of the success of the treatment depends is apt to be lost sight of. But if a student be placed in a bacteriological laboratory with a few gelatine tubes, a few pure cultures, and a microscope, an opportunity is offered to him of grasping the fact that in a tube containing gelatine, protected only by a thin layer of cotton wadding, there can be no development of organic life so long as this plug remains *in situ*; but that when a similar tube is inoculated with any single kind of organism, having seen the seed-tube, he is able to prognosticate with the utmost certainty what will be the nature of the growth and of the changes that will take place in the gelatine as soon as the inoculation has been made and the cotton-wadding plug reinserted. The student has before him a concrete fact. He knows that if the anthrax bacillus is sown the anthrax culture will make its appearance in the gelatine—there is the characteristic naked-eye growth, there are characteristic changes in the gelatine, whilst the microscopic appearances are also readily recognisable. From this it is but a step to an understanding of the fact that in order that the anthrax bacillus may appear in the blood of an animal the seed of the anthrax bacillus must be introduced from outside. When this is associated in his mind with the definite symptoms that characterise the disease the student has laid the foundation of a knowledge of antiseptic surgery which consists in keeping out specific organisms from the cultivation grounds that are offered by open wounds; and he has also grasped the principles that underlie the study of infective diseases, their causation, and their prevention. If not yet essential, it would be at least an exceedingly good thing if every student received a short course of instruction in practical bacteriology; and, although this would naturally fall under the head of practical pathology, the subject has such wide and intimate connexions with, and bearings on, other parts of the curriculum that it might with almost equal propriety be claimed by the chemist, the biologist, the physiologist, the hygienist, the surgeon, and the physician.

The medical practitioner is confronted at every turn by problems which, without some knowledge of bacteria, their life history, and of their effects on the human organism, he is unable to obtain a satisfactory solution; and nothing has been more striking in the evolution of modern medicine and surgery than the intimate relation which every day is being more and more closely traced between specific bacteria and specific forms of disease. Although, as we have already said, it may be impossible for the student to devote any lengthened period to the study of bacteriology, he should at any rate give it sufficient attention to enable him to have at his fingers' ends a certain amount of the technique ready for instant application. Many of the medical schools in the kingdom have already recognised this fact, and in London alone there are several well-equipped bacteriological laboratories where thorough course of instruction can be obtained by the medical student. Guy's Hospital, University College Hospital, and St. Bartholomew's Hospital, for example, have acquired special facilities for carrying on this work; but there is still much room for the more systematic teaching of the subject. In the large university and other schools, especially in Oxford, Cambridge, Victoria, Dublin, Edinburgh, Aberdeen, and Glasgow, the subject is more or less thoroughly taught, but not in all cases practically as is desirable. Bacteriology, however, is a subject of comparatively recent growth, and many who have left their student days behind but one or two had no opportunity of acquiring even the

Digitized by Google

elementary knowledge of the subject, and now feel that it is necessary to make good this deficiency. For preventive medicine may be said to become truly objective when bacteria are recognised as the cause of disease; and there can be little doubt that the great success that has been attained in this country in connexion with our sanitation departments has been largely due to the fact that—sometimes unwittingly, but always very surely—our medical officers of health have aimed at bringing under control all those conditions that are favourable to the growth of micro-organisms. Dirt being matter in the wrong place, sanitary dirt may be looked upon as bacteria in the wrong place; and it is now the object of every sanitarian to bring these bacteria into their right position, receiving their aid in the disintegration of dead organic matter, but preventing them from developing in all places where their presence might be harmful. And how can the medical man, as the guardian of the country's health, be more fitly employed?

Post-graduation courses in bacteriology have, therefore, been in great demand for some years. They have always been successful wherever well conducted, and the demand for this kind of instruction is still increasing. In Berlin, Paris, and Vienna most admirably conducted courses are always going on, but the demand for places in them has become so great that graduates and students have to wait sometimes months and even years before they can be admitted. In London there are facilities for such study at King's College, where there is a regular class of instruction; also in the other medical schools above mentioned; whilst facilities for original investigation are offered at the laboratories of the Conjoint Board of the Royal Colleges of Physicians of London and Surgeons of England and at the British Institute of Preventive Medicine. Bacteriology, though somewhat neglected in this country hitherto, is gradually coming to take its proper position. That it will be popular with students is certain, as it is not only a subject of great value, but also one of extreme interest and even fascination.

ELECTRICITY IN MEDICINE.

THE services which electricity can perform in medicine and surgery are both numerous and varied, and now that they are becoming more generally appreciated by the profession it will be useful to pass in review the present position of medical electricity. This branch of therapeutics has been singularly unfortunate in that it has been grossly abused by people who have made of it a stalking-horse for rampant quackery, and in consequence of these abuses it has tended to fall into disfavour with a large section of the medical profession, and there have been but few men able and willing to make a scientific study of those physiological effects of electrical currents upon which alone their application to therapeutics can find a proper basis.

Electricity has been applied to medicine almost from its first discovery, and at the end of the last and at the beginning of the present century many reports of cures by its means were published. These early cases hardly repay an investigation; many of them seem to have been hysterical in nature, while others are so imperfectly described as to make their diagnosis difficult. Commencing with the electrostatic machine of those days we find that the galvanic battery and the induction coil were each in turn adopted as modes of treatment as soon as invented.

About the year 1850 REMAK in Germany and DUCHENNE in France began to devote themselves to the study of medical electricity, and the former clearly established the important vaso-motor effects which can be produced by the battery current, and applied them with great success to the treatment of joint affections such as rheumatism, rheumatoid arthritis, and sprains, both old and recent; while DUCHENNE in the field of neurology obtained very striking results by the induction coil in the treatment of many forms of paralysis, neuralgia, and other nervous affections.

During the past ten years the impetus given to the study of electricity by its commercial applications has created fresh interest in medical electricity, and there has been much improvement in the apparatus used, particularly in those details of construction which simplify the management of medical batteries and in the introduction of galvanometers for accurate measurement. Fresh methods of treatment have also been proposed, some of which are likely to prove of real value. On the Continent and in the United States electro-therapeutics, as some of its votaries love to call it, is making progress. In France there are two monthly periodicals devoted exclusively to medical electricity, and in America the Electro-therapeutic Association is busily attacking the question of apparatus in order to obtain a series of standard instruments and accessories for the use of its members. England, unfortunately, has as yet hardly begun to treat medical electricity seriously, although the electrical departments at some of the metropolitan hospitals are doing excellent work.

If we examine the physiological basis of medical electricity we find that the chief effects produced upon living tissues by electrical currents may be arranged as follows—viz., stimulating, vaso-motor, electrotonic, and electrolytic effects. All of these are useful in medical practice. The first or stimulating action is the one employed in a very large proportion of all electrical treatment, and it is useful, not merely for its local effects upon nerve and muscle, but also for its action upon the general nutrition of the body. The effects of electricity upon nutrition are at the present time occupying much attention, and general rather than localised electrification is now first in favour.

The high frequency apparatus of TESLA, the modern electrostatic machine of WIMSHURST, and the electric bath with the alternating current of the street mains all have advocates claiming each as the best means for producing general effects on nutrition. Good results have been obtained by all of these methods in such morbid condition as rickets, chlorosis, general debility after exhausting diseases, atonic dyspepsia, in neurasthenia, and in chronic rheumatism and rheumatoid arthritis, and it is probable that the choice of one of these methods is rather to be determined by convenience than by any essential difference existing between them, though we are inclined to give the first place to the electric bath with a properly regulated alternate current from the street mains, because with

Digitized by Google

this form of treatment galvanometric measurements can be used to check the strength of the current employed.

The range of utility of localised electrification is also extending, and one very important point is becoming clear from the systematic work done in the electrical departments of the hospitals—namely, that patient electrical applications extending over long periods of time are able to do many things which might be thought unlikely or impossible by those who judge of electricity only by its immediate effects. There is not much which is instantaneous and there is nothing which is magical about the results of electrical treatment, and those who wish to benefit their patients by electricity must be willing to devote much time and patience to the treatment—for example, the gradual amelioration of symptoms in rheumatoid arthritis under electrical treatment is undoubted, but it is slow; so with infantile paralysis months or even years of treatment may be required for some cases, but the final results are better than can be obtained in any other way, and no case of this disease should be condemned as hopeless until after a long and persevering course of electrical treatment has been given. An objection to medical electricity which is often put forward is that the cases which have improved under the treatment would have improved equally well if nothing had been done. This is by no means a convincing argument, for it might be applied equally well to a large percentage of all therapeutic measures, and if it were true then much of all medical treatment would be superfluous. In the case of electricity, however, all those who have had any real practical experience of it can call to mind numerous instances in which morbid conditions, stationary for long periods when left to themselves, have at once commenced to improve when treated by electricity.

The electrolytic action of the current is of use rather in surgery than in medicine, and is of great service for many small operations, as, for example, the destruction of nævi; in what may be called cosmetic surgery it stands unrivalled as a means of taking away unsightly moles and removing superfluous hairs. In its indirect applications to medical and surgical practice as a means for heating cautery wires and of illuminating small incandescent lamps, electricity plays a humble but very useful part; and the introduction of the cystoscope has already considerably advanced our knowledge of the surgery of the bladder.

While electricity has suffered from neglect at the hands of some its progress has also been hampered by the too great enthusiasm of others. Some of those who have written upon the subject of medical electricity show a grievous indifference to the rules of logic and are far too careless in distinguishing between the *post hoc* and the *propter hoc*. This being the case, it is the duty of all those engaged in this branch of treatment to examine their results rigidly and to make use, so far as is possible, of scientific measurements and tests in recording the progress of their cases. Nor is it necessary to seek to extend unduly the scope of medical electricity so as to include all known disorders in its field of action, but rather to confine it to those in which its value is undoubted.

Of the fact that electrical treatment is at the present time practically restricted to the hands of experts there is doubt, but we do not think that there is any necessity t this should always be so, and it will be far better when ev medical man owns and uses a battery as part of his reg armamentarium. Then the self-styled unqualified "med electrician," male or female, will be no longer requi The employment of such people is a mistake of s importance, and it is a matter in which many practitio show very considerable laxity. Even from the lowest p of view—that of pecuniary profit—it is surely unwis place in the hands of unqualified persons work which w be far better done by members of the medical profes Besides, with unqualified medical electricians there security that they will not sooner or later undertak treatment of cases on their own account, promising cur selling electric or magnetic appliances, or advertising selves in the public prints. Indeed, these things are monly done. An aid to the progress of medical elec would, we think, be afforded by the more frequent int tion of questions upon this subject in the final examin because this, more than anything else, would te increase the general knowledge of the younger m of the profession upon a subject which has remarkable vitality under adverse circumstances certain to become an instrument of great value hands of general practitioners.

THE COST OF MEDICAL EDUCATION.

WE have for several years been in the habit of before our readers an estimate of the cost of medica tion in order that those interested in arriving at tl amount of this expense, which is by no means li such obviously necessary payments as fees, board, a ing, may have some trustworthy materials before which to found a decision about joining a medica We obtained our original information from perso munications as answers to a schedule of questio by the aid of the deans and registrars of th medical schools in the hands of a certain n selected students, who were requested to furni form of replies the data from which a general could be prepared for the guidance of others. the habits of the individual students necess a great, even a preponderating, effect upon tl the returns were sufficiently numerous to yield and it was easy to see that the average r more money in the metropolitan centres th provinces, and that the standard of living and maintaining a given standard varied from plac The most complete statement that we received a provincial student whose great economy in of personal expenses could only be looked u example to distantly follow. It would have to expect that every student could live so fr support himself and pay for rent and food (te clothes, washing, recreation, fees, and even " and "unaccounted" expenses out of the small of £65. But these headings will serve as a which we can discuss the subject gene mising that only general information can be g

Digitized by Google

worth anything, as a medical student as much as any other young man can make his expenses as large as he wishes, while he can only reduce them to the point that is permitted by the circumstances under which he is studying.

The cost of *rent* is the first item to be considered, and naturally enough is a charge which varies greatly with the locality. A student who occupies rooms in desirable quarters of London will pay from £2 to £3 a week on this account alone, while in many large provincial centres lodgings are almost as expensive as they are in London. We may take it a student's rent for furnished apartments ought not to amount to more than one-quarter of the sum that he can fairly count upon receiving as income. If his parents can allow him £150 per annum (a large sum and one that is beyond the power of the parents of many medical students to set aside for one child) his rent should not be more than £1 a week. We are calculating that he will reside at the particular centre of education for about ten months during the year. In London it is not always easy to live near the hospital and obtain lodgings for much less than £1 a week, so that if a student can only expect £2 a week or £6 a month from his parents he is absolutely compelled to spend an imprudent proportion of his income in rent. Clearly none of this applies either to the students who live with their parents, or those who are studying at a university for an arts degree concurrently. Nothing more definite on this subject can be said than that a careful man can live as a medical student on £80 per annum, if he does not spend more than 10*s*. a week on his lodgings; but he will not always find it easy to obtain the lodgings, and every shilling above this weekly sum will make it very hard indeed for him to make both ends meet.

Referring to other centres, the rent of lodgings in Edinburgh is considerably less than in London, but in Dublin it is about the same as in the English metropolis. In Edinburgh there is a sort of residential club known as University Hall, which affords facilities of social intercourse and mutual aid, as, for example, in the lending of books, which is practised systematically amongst the resident students. In addition to these amenities, the institution secures them lodgings at a very moderate monthly rent. Glasgow lodgings again run at about the same level, whilst in Birmingham rent is cheaper still. The cheapest district of which we have any full information is Aberdeen, where both in the matter of rent and of food we have heard of an economy that is altogether exceptional, 3*s*. 6*d*. a week in summer and 4*s*. 6*d*. in winter, the additional shilling representing the cost of fuel to cope with the Scottish winter. In towns like Cork and Leeds the average rises above this limit, but 15*s*. a week is a somewhat high charge. In the Irish provincial towns the rent of rooms is very low, 5*s*. and 6*s*. being by no means below the average. A somewhat higher rent is asked, but still ranging about 10*s*. a week, in English provincial towns, such as Stockton, or Rugby, or Devonport; but residence in these involves constant railway travelling, and would hardly be adapted for the purposes of a student's career, unless some special considerations influenced the decision with which fine questions of comparative expense would not come into competition. The lodging accommodation afforded by residential colleges, hospitals, and the like institutions should be mentioned. But concerning these a word may suffice. The advantages of residence in a college are manifold, but they are chiefly of the intellectual and social kind. The cost is not less than that of private lodgings thriftily selected. There may also be in some instances impatience on the part of the student of the control imposed by the regulations, which are necessarily devised for the orderly conduct of such institutions. Nevertheless, the select society, and even the inevitable restraint, of such institutions are of great service, especially to young students, who have reason to dread nothing more than solitude and an irresponsible control of any considerable proportion of their own time. On the other hand, the cost of board and lodging in such institutions is not greater than the average cost of the same accommodation in private lodgings in their neighbourhood. A plan that involves no inordinate expense is to place a student in the house of a medical practitioner in the neighbourhood of the school which he is attending. It will be found that when the educational facilities thus placed in his way are taken into account, in addition to the mere commercial value of his board and lodging, the arrangement is usually a very economical one. The opportunities for doing this are, of course, not unlimited, but they are sufficiently numerous to merit mention here.

Passing to the next heading, that of *food*, we may observe that here again nothing can be said precisely, but we can indicate the minimum sum that can be spent, and variation from this sum must be dictated by the student's purse. The prevalence of high prices or of low prices, as the case may be, affects such figures very little, and we may say that £30 is, we consider, in London, the least sum that will meet necessary expenditure on food. This again refers only to ten months in the year.

Clothes cannot properly be chargeable to the education account, since the student would in any case be clothed, and the amount expended upon his wardrobe will be determined by his personal habits, and in no sense by his professional studies or occupations.

Lastly, with regard to *fees*, the composition fee which is published by the various schools, and is in a sense a comprehensive charge, may easily be supposed to be more comprehensive than it is. A glance at our tables will show exactly how it is arrived at and what it covers. Broadly it may be said to include all the professorial fees; but it does not include *books* — that is a matter of course. Equally it does not include *instruments*, and these two items together cannot be fairly written down at less than £8 a year in an ordinary case. Many circumstances may occur to falsify this estimate. A successful student may largely supply himself with books by prize winning, or access to a suitable library may minimise his personal requirements in this respect. With instruments, bones, parts for dissection, and the like, the case is somewhat different, and the expenditure under these heads can only be avoided at the expense of the student's education. A niggard hand in such matters makes therefore a grievous mistake, and this should be clearly appreciated at first, otherwise the temptation to undue parsimony will be supported by a grudging mind. Another item which is for very good reason omitted from the composition payment is the *charge for examination fees*. The reason of this

Digitized by Google

will be at once apparent if it is only considered that the teaching bodies and the examining bodies are distinct, and that whereas the composition fee represents a sum payable to institutions of the former class, the examination fees are receivable by institutions exercising the examining function. It will be hard to quarrel with an arrangement which is justified by the importance of paying the fee to the right person. Less obvious, but of the same kind, is the explanation of the circumstance that *tutorial fees* are not included in the composition. Many students pass through their curriculum by the aid of lectures and professorial instruction only. This is very possible when only pass examinations are attempted; but for competitive examinations additional instruction is generally an indispensable preparatory. Such additional instruction must of course be paid for, but its occasional character prohibits its inclusion with the indispensable items in the comprehensive payment.

To sum up, we have this position: The minimum sum that a student must be prepared to spend in London during a year on board and lodging is £60, though £50 will cover his expenditure in these directions in other centres, and less if he is careful. He can save 20 per cent. of this expenditure by living with a fellow-student to their mutual benefit. He must be prepared to spend £10 more at least in books, or instruments, or both. He will be almost the exception if he does not incur one or two extra liabilities in the way of special tuition during his five years' career. He will require another £10 a year as pocket money, and to these figures must be added his fees and the price of his clothes. We do not think that in London any young man should be asked to attempt to maintain himself entirely and pay all necessary fees and expenses of education as well upon a less sum than £100 a year. That many receive less and, to their infinite credit, make it suffice and crown the self-denial of their youth with a success that is sweetened by the struggle to obtain it is undeniable; but many more of their fellow-students receive larger allowances and find them inadequate. Upon individual instances, with their innumerable reasons for special treatment, we do not attempt to dwell, and we desire our readers to remember that, roughly speaking, the figures which we now give for London are a little, perhaps 15 per cent., in excess of those that with the practice of economy would be found to apply to the provinces, Scotland, and Ireland. Our advice is very general and is as follows: If a student cannot command personally or by allowance from his parents £100 per annum, and look to receiving it regularly for at least four out of the five years of his curriculum, we consider that he is rash in these exacting days to embark upon our profession.

SHORTHAND IN MEDICINE.

FROM the time when man first began to express his ideas by means of signs and symbols he must have seen the need of doing so in as brief and expeditious a manner as possible, and this is clearly shown in the evolution of alphabets. It is not known when the art of short writing first originated although some have credited the Egyptians with being its inventors, but it is certain that abbreviated writing or tachygraphy was known to the Romans, and probably to the Greeks at an early date. From the tenth century until nearly the end of the sixteenth all knowledge of the art seems to have been lost, but in 1588 "Characterie: an Arte of Shorte, Swifte, and Secrete Writing by Character, Inuented by Timothie Bright, Doctor of Phisicke," was published. Since that time several good systems have been invented, but phonography—almost the latest—is now in more general use than any of its rivals. One of the first uses to which shorthand was put was, of course, the recording of oratory; but it has been, and is, used in almost all walks of life, the commercial world being perhaps the first to take full advantage of its use in the saving of time and in the expedition of labour. Of its utility in the learned professions there can be no doubt. Amongst lawyers and divines it has been in use for many years, and there are those eminent in the medical profession who attribute much of their success to the fact that they possess a knowledge of shorthand.

To the practitioner who wishes to rapidly take notes of cases or to record facts in his note-book which he has gleaned in reading or by observation, shorthand will be found, not only to greatly economise time, but will change the laborious task of recording notes in longhand into a work of pleasure. Its use by the student is of equal value. In the lecture theatre, in the demonstration rooms, by the bedside, in the out-patients' department, and in a variety of other ways the use of shorthand will enable him to record his experience in less time and in a more convenient manner than by the use of longhand, and, in addition, the information will be ready to his hand when wanted. There is also another advantage, and this not a small one, which the study of phonography confers. Rightly used it has an educational value of its own. In acquiring any kind of knowledge two of the most important habits to develop are attention and method, and both are developed and strengthened by an intelligent use of phonography.

A knowledge of shorthand is one of the greatest helps that a student can have in the study of any profession but in that of medicine, perhaps more than in any other, much will depend upon the way in which the art is used, for unless it is used intelligently it may prove to be one of his greatest hindrances. For example, we can conceive of nothing more useless to the student than a note-book encumbered with his crude attempts to take a verbatim report, and this is generally what the inexperienced person does, or rather attempts to do, with his newly acquired art. Notes such as these are not only useless and a waste of time, but the subsequent endeavour to extract the grain from the chaff is likely to lead him to abandon with disgust what with a little instruction would prove a valuable possession. It is unnecessary here to point out the various ways in which shorthand can be used in medicine, especially as this has been done in two little books published under the auspices of the Society of Medical Phonographers:[1] but apart from its work in mere recording there is another way in which it will be found to be of

[1] The Use of Shorthand by the Student. The Use of Shorthand by the Practitioner. Both issued by the Society of Medical Phonographers and sold by Sir I. Pitman and Sons, 1, Amen-corner, London, E.C., and New York. Price 6d. each.

Digitized by Google

inestimable value. A student may sometimes find it convenient to rearrange the facts contained in his text-book in a manner more congenial to his mental tastes and habits, and shorthand provides a ready means of doing this. It is not expected that a student will copy out the whole of a text-book to suit his own ideas, this would be neither wise nor profitable; but there may be certain methods of tabulating facts which he has been in the habit of using in his preliminary studies, and shorthand will enable him to rearrange his facts in a manner best suited to his own ideas. A book of this kind would have the left-hand page blank for supplemental notes, while the right-hand page would contain the tabulated facts in phonography, with headings and sub-headings in longhand. Such a book properly constructed forms a most useful catalogue of facts presented in a manner most useful for review.

As an example of the value of the art in this connexion the author of one of the books referred to gives an instance of a student at the University of London who took notes of the lectures on systematic medicine given by the present President of the College of Physicians, Sir J. RUSSELL REYNOLDS. These were relied upon for systematic knowledge of medicine; no systematic text-book was used, and to these notes alone, so far as systematic reading was concerned, he owed the gold medal which was given at the M.D. examination. Of course, in this case much depended upon the ability of the teacher whose methodical and accurate style is reflected in the notes of the student, and when the lecturer goes from point to point in logical order the notes taken by the student will be of the utmost service. As has already been said, much depends on the way in which shorthand is used, and in "The Use of Shorthand by the Student" an endeavour is made to furnish the student with the necessary information to enable him to use his shorthand intelligently, and the examples by which it is illustrated bear the stamp of the practical man and teacher. The student who makes himself thoroughly acquainted with the advice and examples in this book will find himself in possession of a power which will help him to raise himself far above his fellows who do not possess this knowledge. Indeed, as the author remarks: "Of two students of equal ability, character, and knowledge, of whom one knows shorthand and the other does not, it is certain that the one who knows shorthand will far exceed the other who does not." Excellent examples are given of notetaking in almost every department of the student's curriculum, and the book is one we can thoroughly recommend not only to students of medicine, but to the student of any branch of science. But here a word of warning is necessary. Unless the student can read and write shorthand with facility at the commencement of his studies, he must not expect to obtain the help from it here indicated. It is possible that he may be able to devote say half an hour each day to its acquisition, and if this is done under the guidance of a competent teacher phonography can soon be mastered, but the time which should be devoted to his professional studies should not be encroached upon. If he is quite ignorant of the art when he first enters upon his medical studies it would be wise to wait till the vacation before attempting to learn shorthand. The other little book to which we have alluded is perhaps after all the most important; for it is after the student days are over and the medical man is fairly launched in his profession that shorthand can be utilised in its highest degree of power. This is admirably brought out in "The Use of Shorthand by the Practitioner." In this little work the best way of making and storing notes for future use, based on the experience of medical phonographers whose extensive use of shorthand gives weight to their opinions, is clearly pointed out; specimen pages of actual case-books &c. are given, together with some valuable hints on indexing.

As to the acquisition of phonography it may be self-taught by those who have the necessary ability and energy, but it is far better to obtain the services of a competent teacher. Many excellent text-books and manuals of instructions are published, and there is quite a library of books issued in the phonographic characters, but there is still room for another which might bear the title of "Pitfalls of the Self-learner," and until this is published it is unwise for the student to attempt to acquire the system without at least the assistance of one who already knows phonography thoroughly.

ALLEGED CHOLERA AT GRIMSBY.

THE news as to alleged cholera at Grimsby has revived the suspicion which in 1893 was associated with the sanitary administration of that borough. Happily, though two cases which clinically resembled cholera have terminated fatally, there appear for the moment to be no further attacks of an equally suspicious character; and the material supplied to Dr. Klein for bacteriological examination has not afforded positive evidence that the disease in question was Asiatic cholera. But the attitude of the town council can hardly fail to cause apprehension. Apparently remembering the significance of diarrhœa in connexion with the beginnings of the 1893 epidemic, the notification of this disorder was in progress in the borough, and during the third week of August an alarming increase took place. The town council thus received just the information that they sought, but when it came they actually stopped all further diarrhœa notification, and this at the very instant that it had become of the highest value to them. What could have induced a sanitary authority to take so retrograde a step at such an important juncture remains unexplained; but the fact that they did act thus may be accepted as a sufficient explanation of their decision to exclude reporters at a later meeting held after the visit of Dr. Theodore Thomson of the Local Government Board, at which meeting the notification was apparently ordered to be resumed. So far as we can learn the case of fatal choleraic diarrhœa—or whatever it was—remained unknown to the council almost up to the time of death by reason of this unaccountable action in stopping their sources of information. Fortunately, Grimsby will not be allowed to hide matters thus, for it appears that as early as Thursday of last week the Local Government Board became suspicious as to what was going on there, and next day a medical inspector arrived unexpectedly on the spot. He still remains there, and it is to be hoped that he will see that the town council not only act efficiently, but act openly in regard to a matter that is of importance to England as a whole. Recrudescence of cholera in Grimsby is a thing that might well occur in a season such as we have recently experienced, and we earnestly trust that no trade or other considerations will be allowed to stand in the way of the earliest and most efficient action should any further indications of danger arise. Hull also received the visit of a medical inspector last week on account of some excess in diarrhœa mortality, but, as has been the case before, an efficient administration has thus far been able so to deal with the diarrhœal prevalence that no anxiety appears to exist as to the future.

SESSION 1895-96.

GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION OF THE UNITED KINGDOM.

Registration of Medical Students.—The following are the General Medical Council's Regulations in reference to the registration of students in medicine:—

Every medical student shall be registered in the manner prescribed by the General Medical Council. No medical student shall be registered until he has passed a preliminary examination as required by the General Medical Council, and has produced evidence that he has commenced medical study. The commencement of the course of professional study recognised by any of the qualifying bodies shall not be reckoned as dating earlier than fifteen days before the date of registration. The registration of medical students shall be placed under the charge of the branch registrars. Every person desirous of being registered as a medical student shall apply to the branch registrar of the division of the United Kingdom in which he is residing; and shall produce or forward to the branch registrar a certificate of his having passed a preliminary examination as required by the General Medical Council, and *evidence that he has commenced medical study*. The branch registrar shall enter the applicant's name and other particulars in the Students' Register, and shall give him a certificate of such registration. Each of the branch registrars shall supply to the several qualifying bodies, medical schools, and hospitals, in that part of the United Kingdom of which he is registrar, a sufficient number of blank forms of application for the registration of medical students. To the several qualifying bodies it is recommended that, in the case of candidates who commenced study after Jan. 1st, 1892, the final examination in Medicine, Surgery, and Midwifery should not be passed before the close of the fifth year of medical study. The questions of ante-dating and exceptional recognition of Preliminary Examinations not on the Council's list are now dealt with by the Students' Registration Committee, which meets in May and November and reports all such cases to the Council.

The Preliminary Examination in General Education, required to be passed previously to registration as a Medical Student, shall be as follows:—

"1. English language, including grammar and composition. 2. Latin, including grammar, translation from specified authors, and translation of easy passages not taken from such authors. 3. Mathematics, comprising (*a*) arithmetic, (*b*) algebra, as far as simple equations, inclusive; (*c*) geometry, the subject matter of Euclid, Books I., II., and III., with easy deductions. 4. One of the following optional subjects: (*a*) Greek, (*b*) French, (*c*) German, (*d*) Italian, (*e*) any other modern language, (*f*) [illegible]."

The Council will not in future accept any certificate of pass in Preliminary Examination in General Education unless the whole of the subjects included in the Preliminary Examination required by the Council for Registration of Students of Medicine have been *passed at the same time*, but this rule shall not apply to those who, previously to Jan. 1st, 1892, have passed a part of any Preliminary Examination recognised by the Council; provided that a certificate of having passed a University Examination required for graduation in Arts, or a Senior or higher Local University Examination, or a Senior Grade Examination of the Intermediate Education Board of Ireland, or the Leaving Certificate Examination (Honours and Higher Grade) of the Scottish Education Department wherein the specified subjects of General Education are included, may be recognised for the purpose of registration.

Professional Education.—1. "The course of professional study after registration should occupy at least five years, conditionally."

2. "The first four of the five years should be passed at a School or Schools of Medicine recognised by any of the Licensing Bodies mentioned in Schedule A of the Medical Act (1858), provided that the first year may be passed at a University or Teaching Institution, recognised by any of the Licensing Bodies, where the subjects of Physics, Chemistry, and Biology are taught."

3. "Graduates in Arts or Science of any University recognised by the Medical Council who shall have spent a year in the study of Physics, Chemistry, and Biology, and have passed an examination in these subjects for the degrees in question, should be held to have completed the first of the five years of medical study."

4. "The fifth year should be devoted to clinical work at one or more of such public hospitals or dispensaries, British or foreign, as may be recognised by any of the medical authorities mentioned in Schedule A of the Medical Act (1858), provided that of this year six months may be passed as a pupil to a Registered Practitioner holding a public appointment, or possessing such opportunities of imparting practical knowledge as shall be satisfactory to the medical authorities."

5. "The Regulations of the Examining Bodies and of the schools should be so framed that attendance on systematic courses may be concluded at the end of the fourth year of study, so as to permit of the student devoting the fifth year to clinical work, as defined in Resolution 4."

6. "The regulations requiring attendance on systematic Courses of Lectures ought not to require attendance on more than three Lectures weekly in any one Course."

7. "Due time should be set aside for Practical Work in the various subjects. Attendance on a Practical Course should be carefully ascertained and certified. By a Practical Course is understood one in which work is done by the student himself, under the direction of a duly qualified teacher."

8. "In order to promote a practical system of Clinical Teaching the Regulations should specify 'Hospital Practice with Clinical Instruction.' Ample time should be set aside for Hospital Work, and means should be taken to ascertain regularity of attendance in the Wards and Out-patient Departments. Every candidate for the Final Professional Examination at the end of the fifth year should be required to give evidence that he has had sufficient opportunities of practical study."

This Resolution relates to such offices as the following: Clinical Medical Clerkship and Surgical Dressership—either for in- or out-patients; Obstetrical Clerkship; post-mortem Clerkship.

9. "No qualification in Medicine ought to be granted without evidence of clinical instruction in infectious diseases."

Professional Examination.—10. "With the view of securing attention to practical work in Education, the time devoted to the practical part of the examinations in all the subjects should be extended."

11. "The examination in the Elements of Physics (including Mechanics), Chemistry, and Biology should be passed before the beginning of the second winter session." With references to this Resolution the Council, on Dec. 4th, 1894, adopted the following Resolution:—

"A student who has previous to registration attended a course or courses of study in one or all of the subjects, Physics, Chemistry, or Biology, in any University, School of Medicine, or Teaching Institution recognised by any of the Licensing Bodies, may without further attendance be admitted to examination in these subjects; provided always that such course or courses shall not be held to constitute any part of the five years' course of professional study."—*Minutes*, vol. xxxi., p. 163.

12. "Antecedent to the Final Examination there should be three Professional Examinations, arranged in such manner as to secure due continuity and sequence of study."

13. "All examinations, except the Final Examination in Medicine, Surgery, and Midwifery, should be passed before the final year intended for clinical work."

14. "The Final Examination in Medicine, Surgery, and Midwifery must not be passed before the close of the fifth year of medical study."

15. "The system of compensation as between the three different subjects of the qualifying examinations—viz., Medicine, Surgery, and Midwifery—is contrary to the intention of the Medical Act (1886), and the Council directs the attention of the several medical authorities to this fact."

16. "The marks for the written and oral examinations in Medicine and Surgery at the Final Examination should not exceed those for the clinical and practical portions of the examination."

17. "Seeing that the practice of different authorities varies on the question whether a student who fails to satisfy the Examiners in each of the several subjects of Medicine, Surgery, and Midwifery should be referred on all of them, or only on those in which he fails, the Council recommends that some general principle should be adopted with reference to this question; and suggests that a percentage of not less than 60 marks on each of any two subjects—supposing that the pass requirement be 50 per cent.—should exempt from re-examination in those two subjects."

18. "The Council recommends to the Examining Bodies the use of a percentage system of marks; and, for facilitating the work of the inspectors appointed by the Council, the adoption of a uniform pass mark of 50 per cent."

19 "With regard to the Course of Study and Examinations which persons desirous of qualifying for the medical

Digitized by Google

profession shall go through in order that they may become possessed of the requisite knowledge and skill for the efficient practice of the profession, the Council now resolves that, in its opinion, the following conditions ought to be enforced without exception on all who commence their medical studies at any time after Jan. 1, 1892 :—

(*a*) "With the exceptions provided for under Resolution 3, the period of professional study, between the date of registration as a medical student and the date of Final Examination for any diploma which entitles its bearer to be registered under the Medical Acts, must be a period of *bonâ-fide* study during not less than five years:

(*b*) "In every course of professional study and examinations the following subjects must be contained: (i.) Physics, including the Elementary Mechanics of Solids and Fluids, and the rudiments of Heat, Light, and Electricity; (ii.) Chemistry, including the principles of the science and the details which bear on the study of Medicine; (iii.) Elementary Biology; (iv.) Anatomy; (v.) Physiology; (vi.) Materia Medica and Pharmacy; (vii.) Pathology; (viii.) Therapeutics; (ix.) Medicine, including Medical Anatomy and Clinical Medicine; (x.) Surgery, including Surgical Anatomy and Clinical Surgery; (xi.) Midwifery, including Diseases peculiar to Women and to new-born Children; (xii.) Theory and Practice of Vaccination; (xiii.) Forensic Medicine; (xiv.) Hygiene; (xv.) Mental Disease."

*** It is to be understood, as regards the above-mentioned subjects, that the Council offers no opinion as to the manner in which the subjects should be combined or distributed for purposes of teaching or examination.

(*c*) "At successive stated times during the first four years of the course of study all students must pass such intermediate examinations as will test their proficiency in the successive earlier branches of medical education, and, while tending to promote a due sequence in the medical studies, will also tend to lighten the final examination of matters which can properly be spared from it."

W. J. C. Miller, B.A., Registrar of the General Council and of the Branch Council for England, 299, Oxford-street, London, W.—James Robertson, Registrar of the Branch Council for Scotland, 1, George-square, Edinburgh.—R. L. Heard, M.D., Registrar of the Branch Council for Ireland, 35, Dawson-street, Dublin.

I.—UNIVERSITIES IN THE UNITED KINGDOM.

The following is a list of Examining Bodies whose examinations in general education fulfil the conditions of the Medical Council as entitling to registration as a medical or dental student the applicant producing satisfactory evidence that he has passed them :—

University of Oxford.—Junior Local Examinations; Certificate to include Latin and Mathematics, and also one of these optional subjects—Greek, French, German. Senior Local Examinations; Certificate to include Latin and Mathematics. Responsions. Moderations. Examination for a degree in Arts.

University of Cambridge.—Junior Local Examinations; Certificate to include Latin and Mathematics, and also one of these optional subjects—Greek, French, German. Senior Local Examinations; Certificate to include Latin and Mathematics. Higher Local Examinations. Previous Examination. Examination for a degree in Arts.

University of Durham.—Examination for Certificate of Proficiency. Examination for students at the end of their first year. Examination for a degree in Arts.

University of London.—Matriculation Examination. Preliminary Scientific (M.B.) Examination. Examination for a degree in Arts or Science.

Victoria University.—Preliminary Examination; Latin to be one of the subjects. Entrance Examination in Arts, to include all the subjects required.

University of Wales.—Matriculation Examination; the whole of the Examination to be passed at the same time, and to include one of the optional subjects required by the Council.

University of Edinburgh.—Local Examinations (Junior Certificate); Certificate to include English Literature, Arithmetic, Algebra, Geometry, Latin, and also one of these optional subjects—Greek, French, German. Local Examinations (Senior Certificate); Certificate to include English Literature, Arithmetic, Algebra, Geometry, Latin, and also one of these optional subjects—Greek, French, German. Preliminary Examination for Graduation in Science or Medicine and Surgery. Examination for a degree in Arts.

University of Aberdeen.—Local Examinations (Junior Certificate); Certificate to include all the subjects required. Local Examination (Senior Certificate); Certificate to include English Literature, Arithmetic, Algebra, Geometry, Latin, and also one of these optional subjects—Greek, French, German. Preliminary Examination for Graduation in Medicine or Surgery. Examination for a degree in Arts.

University of Glasgow.—Local Examinations (Junior Certificate); Certificate to include all the subjects required. Local Examinations (Senior Certificate); Certificate to include English Literature. Arithmetic, Algebra, Geometry, Latin, and also one of these optional subjects—Greek, French, German. Preliminary Examination for Graduation in Medicine or Surgery. Examination for a degree in Arts.

University of St. Andrews.—Local Examinations (Senior Certificate); Certificate to include English Literature, Arithmetic, Algebra, Geometry, Latin, and also one of these optional subjects—Greek, French, German. Local Examinations (Junior Certificate), to include all the subjects required. Preliminary Examination for Graduation in Medicine or Surgery. Examination for a degree in Arts.

University of Dublin.—Public Entrance Examination. General Examination at end of Senior Freshman year. Examination for a degree in Arts.

Royal University of Ireland.—Matriculation Examination.

Oxford and Cambridge Schools Examination Board.—Certificate to include the following subjects, an adequate knowledge of English Grammar and Orthography, as shown in the course of the examination, to the satisfaction of the examiners, being held as conforming to the requirements of the Medical Council in regard to those subjects: (*a*) Arithmetic, including Vulgar and Decimal Fractions; (*b*) Algebra, including Simple Equations; (*c*) Geometry, including the first two books of Euclid; (*d*) Latin, including Translation and Grammar; (*e*) Also one of these optional subjects—Greek, French, German.

II.—OTHER BODIES NAMED IN SCHEDULE (A) TO THE MEDICAL ACT.

Apothecaries' Society of London.—Examination in Arts.[1]

Royal Colleges of Physicians and Surgeons of Edinburgh.[2]—Preliminary (combined) Examination in General Education.

Faculty of Physicians and Surgeons of Glasgow.—Preliminary Examination in General Education.[2]

Royal Colleges of Physicians and Surgeons in Ireland.—Preliminary Examination; Certificate to include Mathematics.[1]

III.—EXAMINING BODIES IN THE UNITED KINGDOM NOT INCLUDED IN SCHEDULE (A) TO THE MEDICAL ACT, 1858.

College of Preceptors.—Examination for a First Class Certificate, or Second Class Certificate of First or Second Division, Algebra, Geometry, Latin, and either a Modern Language, or Greek, or Logic, having been taken. Preliminary Examinations for Medical Students.

Intermediate Education Board of Ireland.—Junior Grade Examination; Middle Grade Examination; Senior Grade Examination (Certificate in each case to include all the subjects required).

Educational Institute of Scotland.—Preliminary Medical Examination.

Scotch Education Department.—Leaving Certificates in each Grade and in Honours.

IV.—INDIAN, COLONIAL, AND FOREIGN UNIVERSITIES AND COLLEGES.

"The Certificates from Indian, Colonial, and Foreign Universities and Colleges must contain evidence that the Examination has been conducted by or under the authority of the Body granting it, includes all the subjects required by the General Medical Council, and states that all the subjects of Examination have been passed in at one time; and copies of the form of the required Certificate will be supplied by the Registrar of the Council for the purpose. In the case of Natives of India or other Oriental countries, whose vernacular is other than English, an Examination in a Classic Oriental Language may be accepted instead of an Examination in Latin."

REGULATIONS
OF THE
MEDICAL EXAMINING BOARDS IN THE UNITED KINGDOM.

UNIVERSITY OF OXFORD.

THERE are two degrees in Medicine, B.M. and D.M., and two degrees in Surgery, B.Ch. and M.Ch.

The B.M. and B.Ch. degrees are granted to those

[1] The Council has recommended that these examinations be discontinued.

[2] These examinations are conducted by the Educational Institute of Scotland.

Digitized by Google

members of the University who have passed the Second Examination. Graduates in Arts (B.A. or M.A.) are alone eligible for these two degrees. In order to obtain the degrees of B.M. and B.Ch. the following examinations must be passed:—1 Preliminary subjects: Mechanics and Physics, Chemistry, Animal Morphology and Botany. 2. Professional. (*a*) First Examination: Subjects—Organic Chemistry, unless the candidate has obtained a first or second class in Chemistry in the Natural Science School; Human Physiology unless he has obtained a first or second class in Animal Physiology in the Natural Science School; Human Anatomy, and Materia Medica with Pharmacy. (*b*) Second Examination: Subjects—Medicine, Surgery, Midwifery, Pathology, Forensic Medicine with Hygiene. The approximate dates of the examinations are as follows:—Preliminaries—Mechanics, Physics and Chemistry, November and June; Animal Morphology and Botany, December and March; Professional (First and Second B.M.), June and December.

The degree of D.M. is granted to Bachelors of Medicine of the University—(1) who took the degree of B.M. previously to the end of Trinity Term, 1886, provided they have spent three years in the practice of Medicine after taking that degree, and have composed a dissertation on some medical subject approved by the Regius Professor of Medicine, before whom it must be read in public; (2) who took the degree of B.M. subsequently to the end of Trinity Term, 1886, provided they have entered their thirty-ninth term and have composed on some medical subject a dissertation which is approved by the professors in the Faculty of Medicine and examiners for the degree of B.M. whose subject is dealt with. A book published within two years of the candidate's application for the degree may be substituted for a dissertation. The degree of M.Ch. is granted to Bachelors of Surgery of the University who have entered their twenty-seventh term, who are members of the surgical staff of a recognised hospital, or have acted as Dresser or House Surgeon in such a hospital for six months, and who have passed an examination in Surgery, Surgical Anatomy, and Surgical Operations. This examination is held annually, in June, at the end of the Second B.M. Examination.

The First Examination for the degrees of B.M. and B.Ch. may be passed as soon as the Preliminary Scientific Examination has been completed. The subjects of this examination may be presented separately or in any combination or in any order, provided Anatomy and Physiology be passed together.

The Second Examination may be passed after the completion of the first. Before admission to the Second Examination candidates must present Certificates of instruction in Infectious and Mental Diseases, and of attendance on Labours, and of proficiency in the practice of Vaccination.

Scholarships, &c.—Scholarships in some branch of Natural Science (Chemistry, Physics, Biology) of the average value of £80 per annum, tenable for four years and renewable under certain conditions for a fifth year, as well as Exhibitions of a less annual value, are awarded after competitive examination every year by some, from time to time by other, Colleges. Notices of vacancy, &c., are published in the *University Gazette*. In February there is competed for annually, by those who, having obtained a first-class in any school (Moderations or final) or a Scholarship or Prize open to general competition in the University, have passed all the examinations for the degree of B.A., one Radcliffe Travelling Fellowship. It is tenable for three years, and is of the annual value of £200. The examination is partly scientific, partly medical. The holder must travel abroad for the purpose of medical study. A Rolleston Memorial Prize is awarded once in two years to members of the Universities of Oxford and Cambridge of not more than ten years' standing for an original research in some Biological subject, including Physiology or Pathology.

More detailed information may be obtained from the University Calendar; the Examination Statutes, 1894, which contain the official schedules of the several subjects of examination in both Arts and Medicine; from the Student's Handbook to the University; from the Regius Professor of Medicine; and from the Professors in the several departments of science.

UNIVERSITY OF CAMBRIDGE.

The student must enter at one of the Colleges, or as a non-collegiate student, and keep nine terms by residence in the University. He must pass the Previous Examination in Classics and Mathematics, which may, and should if possible, be done immediately on coming into residence in October, or, what is better, obtain exemption through the Oxford and Cambridge Schools Examination Board or the Cambridge Local Examinations, before commencing residence. He may then devote himself to medical study in the University, attending the hospital and the medical lectures, dissecting, &c. Or he may, as nearly all students now do, proceed to take a degree in Arts, either continuing mathematical and classical study and passing the ordinary examinations for B.A., or going out in one of the Honour Triposes. The Natural Sciences Tripos is the most appropriate, as some of the subjects are practically the same as those for the first and second M.B. examinations.

For the degree of *Bachelor of Medicine (M.B.)* five years of medical study are required. This time may be spent in Cambridge or at one of the recognised Schools of Medicine. The first three or four years are usually spent in Cambridge, the student remaining in the University till he has passed, say, the examination for the Natural Sciences Tripos and the first and second examinations for M.B. Cambridge being now a complete School of Medicine, all the requisite lectures and hospital practice may be attended here, and many students remain to attend lectures and hospital practice until they have passed the first part of the third examination for M.B. The supply of subjects for Dissection, Practical Surgery, &c., is unusually abundant.

There are three examinations for M.B. The *first* in Chemistry and other branches of Physics, and in Elementary Biology. These parts may be taken together or separately. The *second* in Human Anatomy and Physiology and in Pharmaceutical Chemistry. These may be taken together or separately. The *third* may also be taken in two parts viz., (1) Principles and Practice of Surgery (with Operative and Clinical Surgery) and Midwifery and Diseases of Women; and (2) Pathology, Principles and Practice of Medicine, Elements of Hygiene, Medical Jurisprudence and Mental Diseases. The examinations are partly in writing, partly oral, and partly practical, in the hospital, in the dissecting-room, and in the laboratories. An Act has to be kept in the Public Schools, by the candidate reading original dissertation composed by himself on some subject approved by the Regius Professor of Physic.

As Operative and Clinical Surgery now form parts of the third M.B. examination candidates who have passed the parts of that examination are admitted to the degree of *Bachelor of Surgery (B.C.)* without separate examination and without keeping an Act.

The degree of *Doctor in Medicine* may be taken four years after that of M.B., or four years after that of B.C. An Act has to be kept, consisting of an original thesis sustained in the Public Schools, with *viva-voce* examination and an extempore Essay has to be written on some subject relating to Physiology, Pathology, the Practice of Medicine or State Medicine.

For the degree of *Master in Surgery (M.C.)* the candidate must have passed all the examinations for B.C. and is required to pass an examination in Surgical Anatomy, Surgical Operations, Pathology and the Principles and Practice of Surgery, and to write an extempore Essay on a Surgical Subject. Before he can be admitted to this examination two years at least must have elapsed from the time when he completed all required for the degree of B.C.

An abstract of the Regulations and Shedules of the examinations in Chemistry, Physics, Biology, and Pharmacy may be obtained upon sending a stamped and addressed envelope to the Registrary, Cambridge. Full information is contained in the *Cambridge University Calendar*.

UNIVERSITY OF LONDON.

The *Matriculation Examination*.—Candidates for degree in this University must have passed the Matriculation Examination. No exemption either from Matriculation or from subsequent examinations is allowed on account of degrees obtained at other Universities or of examinations of other examining bodies that may have been passed. The examinations take place twice in each year—on the first Monday in January and the second Monday in June, but may be held not only at the University of London

Digitized by Google

under special arrangement, in other parts of the United Kingdom or in the colonies. Every candidate must, not less than five weeks before the commencement of the examination, apply by postcard to the Registrar for a form of entry, which must be returned not less than four weeks before the commencement of the examination, accompanied by a certificate showing that the candidate has completed his sixteenth year, and by his fee for the examination. A certificate from the Registrar-General in London or from the superintendent registrar of the district, or a certified copy of the baptismal register, is required in every case in which it can possibly be obtained. In other cases a declaration of the candidate's age, made before a magistrate by his parent or guardian, or by the candidate, if of full age, will be accepted. As candidates cannot be admitted after the list is closed, any candidate who may not have received a form of entry within a week after applying for it should communicate immediately with the Registrar, stating the exact date of his application and the place where it was posted. Every candidate must pay a fee of £2, and if he withdraws his name, or fails to present himself at the examination, or fails to pass it, the fee shall not be returned to him, but he shall be allowed to enter for any subsequent matriculation examination upon payment at every such entry of an additional fee of £1, provided that he comply with the other regulations. Candidates must show a competent knowledge of: 1. Latin. (The subjects for January, 1896: Ovid, Heroides, I., II., III., V., VII., XII.; for June, 1896: Cicero, De Amicitia and In Catilinam III.) 2. One of the following languages: Greek, French, German, Sanskrit, Arabic. (No credit will be given for more than one, and candidates desiring to be examined in the last two must give two months' notice to the Registrar.) The Greek subjects for January, 1896: Xenophon Anabasis, Book VII.; for June, 1896: Euripides, Andromache. 3. The English Language, English History, and Geography. 4. Mathematics (Elementary). 5. Mechanics (Elementary). 6. One of the following branches of science: Chemistry, Heat and Light, Magnetism and Electricity, Botany. (No credit will be given for more than one of these subjects. The examination in Botany is only held in the United Kingdom. Candidates in any one of the optional Branches of Science will find it an advantage to have obtained some elementary instruction in the practical use of apparatus.) A pass certificate signed by the Registrar is delivered to each successful candidate after the report of the examiners shall have been approved by the Senate. The first six candidates in the Honours Division, of not more than twenty years of age at the commencement of the examination, shall respectively receive an exhibition or a prize. Any candidate obtaining a place in the Honours Division at the matriculation examination in January shall be admissible to the intermediate examination either in Arts or in Science in the following July.

Provincial Examinations for Matriculation.—These examinations are appointed by the Senate from time to time upon the application of any city, institution, or college desiring to be named as a local centre for one or more examinations, and are carried on simultaneously with the examinations in London under the supervision of sub-examiners also appointed by the Senate. Candidates wishing to be examined at any provincial centre must give notice upon their forms of entry to the Registrar of the University, who will then make all necessary arrangements. Besides the University fee, a fee usually varying from £1 to £2 is charged by the local authorities, and must be paid *at the local centre* immediately before the commencement of the several examinations. The answers of the candidates at the provincial examinations are reviewed by the examiners at the same time as the answers of the candidates examined in London, and a list of the candidates who have passed at each provincial examination is published at the time fixed by the regulations at the place were such examination has been held. The January Matriculation Examinations, 1896 will be held at:—Birmingham: The Mason Science College. Bristol: The Merchant Venturers' Technical College. Cardiff: Dames Street College (for University College) Glasgow: The Training College, New City-road. Leeds: The Yorkshire College. Newcastle-on-Tyne: Rutherford College. Plymouth: The Public School. Portsmouth: The Grammar School. The June, 1896, Matriculation Examination will be held at:—Aberystwith: University College. Bangor: University College. Birmingham: The Mason Science College. Bristol: University College Cardiff: University College. Edinburgh: The Heriot-Watt College. Leeds: The Yorkshire College. Liverpool: University College. Manchester: The Owens College. Newcastle-on-Tyne: Rutherford College. Nottingham: University College. Plymouth: The Public School. Sheffield: Firth College.

The *Preliminary Scientific (M.B.) Examination.*—Professional studies pursued before the whole of this examination has been passed will not count towards the course required for the M.B. degree. The examination takes place twice in each year, once for Pass and Honours, commencing on the third Monday in July, and once for Pass candidates, only, commencing on the third Monday in January. Every candidate must, not less than five weeks before the commencement of the examination, apply by postcard to the Registrar for a form of entry, which must be returned not less than four weeks before the commencement of the examination, accompanied by the candidate's fee of £5. The subjects of the Preliminary Scientific Examination are divided into two sections: (1) Chemistry and Physics, (2) General Biology. Chemistry includes a written examination in Inorganic Chemistry and a *viva-voce* examination in Qualitative Analysis. Physics implies a knowledge of acoustics, heat, magnetism, electricity, and optics. General Biology comprises a knowledge of the elements of zoological (vertebrate or invertebrate) and botanical morphology physiology and embryology. Candidates shall be allowed to enter for the whole examination or for either section. Candidates who present themselves for the two sections together shall be credited with either section in which they may have passed, although they may have failed to pass in the other, but no such candidate shall be placed in the Honours List. Candidates must bear in mind that the standard of attainment for the Honours examination is much higher than that for the Pass examination; and they should therefore exercise due caution in making their choice, to which they will be required to adhere. A candidate who has entered for the Pass examination will not be allowed to take the Honours papers; and only under special circumstances will a candidate who has entered for Honours in any subject be transferred to the Pass examination in that subject. The fee of £5 covers the whole of the examination, whether taken altogether or in sections.

Provincial Examinations for the Preliminary Scientific (M.B.) Examination.—These examinations are appointed by the Senate from time to time upon precisely the same arrangements as those made for the Provincial Matriculation examinations. The practical examinations in chemistry are conducted at the provincial centres, but all candidates must attend at the University for the practical examinations in Physics and Biology.

Bachelor of Medicine.—Every candidate for the degree of Bachelor of Medicine will be required—1. To have passed the Matriculation Examination in this University not less than five years previously. 2. To have passed the Preliminary Scientific (M.B.) Examination not less than four years previously. 3. To have been engaged in his professional studies during four years subsequently to passing the Preliminary Scientific Examination[3] at one or more of the medical institutions or schools recognised by this University, one year at least of the four being spent in one or more of the recognised institutions or schools in the United Kingdom. 4 To pass two examinations in Medicine.

Intermediate Examination.—The Intermediate Examination in Medicine takes place twice in each year—once for Pass and Honours, commencing on the second Monday in July, and once for Pass candidates only, commencing on the third Monday in January. The subjects of the examination are Anatomy, Physiology and Histology. Organic Chemistry, Materia Medica, and Pharmaceutical Chemistry. The standard of attainment required for Honours is much higher than for a Pass. No candidate shall be admitted to this examination unless he have passed the Preliminary Scientific Examination at least two years previously, and have produced certificates to the following effect:—1. Of having completed his nineteenth year. 2 Of having, subsequently to having passed the Matriculation Examination, been a student during two years at one or more of the medical institutions or schools recognised by this University, and of having attended a course of lectures on

[3] Candidates who passed the Matriculation Examination in January, 1885, or previously, will be allowed to date the commencement of their professional studies, as heretofore, from that examination.

Digitized by Google

each of three of the subjects in the following list: Descriptive and Surgical Anatomy, Physiology and Histology, Pathological Anatomy, Materia Medica and Pharmacy, General Pathology, General Therapeutics, Forensic Medicine, Hygiene, Obstetric Medicine and Diseases peculiar to Women and Infants, Surgery, Medicine. 3. Of having, subsequently to having passed the Preliminary Scientific Examination, dissected during two sessions. 4. Of having, subsequently to having passed the Preliminary Scientific Examination, attended a course of Practical Chemistry, comprehending practical exercises in conducting the more important processes of general and pharmaceutical chemistry, in applying tests for discovering the adulteration of articles of the Materia Medica and the presence and nature of poisons, and in the examination of mineral waters, animal secretions, urinary deposits, calculi, &c. 5. Of having attended to Practical Pharmacy and of having acquired a practical knowledge of the preparation of medicines. These certificates (as is the case also with all the certificates hereinafter mentioned) must be transmitted to the Registrar at least four weeks before the commencement of the examination. Fee for this examination, £5.

M.B. Examination.—The M.B. Examination takes place twice in each year—once for Pass and Honours, commencing on the last Monday in October, and once for Pass candidates only, commencing on the first Monday in May. The subjects of the examination are General Pathology General Therapeutics, Hygiene, Surgery, Medicine, Obstetric Medicine, and Forensic Medicine. No candidate will be admitted to this examination within twenty-one months of the time of his passing the Intermediate Examination unless he be a registered medical practitioner of not less than three years' standing, in which case he must produce a certificate of having gone through the required course of training at some time previously. Every candidate must produce certificates:—1. Of having passed the Intermediate Examinations. 2. Of having attended a course of lectures on each of two of the subjects enumerated above in the regulations for that examination for which the candidate had not on that occasion presented certificates. 3. Of having conducted at least twenty labours. Certificates on this subject will be received from any legally qualified practioner in Medicine. 4. Of having attended the Surgical Practice of a recognised hospital or hospitals during two years, with clinical instruction and lectures on Clinical Surgery. 5. Of having attended the Medical Practice of a recognised hospital or hospitals during two years, with clinical instruction and lectures on Clinical Medicine, including, in and after October, 1895, Infectious Diseases and Lunacy. 6. Of having, after having attended Surgical and Medical Hospital Practice for at least twelve months subsequently to passing the Intermediate Examination in Medicine, attended to Practical Medicine, Surgery, or Obstetric Medicine, with special charge of patients, in a hospital, infirmary, dispensary, or parochial union during six months, such attendance not to be counted as part of either the Surgical or the Medical Hospital Practice prescribed in Clauses 4 and 5. 7. Of having acquired proficiency in Vaccination. Certificates on this subject will be received only from the authorised vaccinators appointed by the Privy Council. The fee for this examination is £5.

Bachelor of Surgery.—The examination for the degree of Bachelor of Surgery takes place once in each year, and commences on the Tuesday following the first Monday in December. Candidates must produce certificates to the following effect:—1. Of having passed the examination for the degree of Bachelor of Medicine in this University. 2. Of having attended a course of instruction in Operative Surgery and of having operated on the dead subject. The subjects of the examination are Surgical Anatomy and Surgery. Fee £5.

Master in Surgery.—The examination for the degree of Master in Surgery takes place once in each year, and commences on the first Monday in December. Candidates must produce certificates to the following effect: 1. Of having taken the degree of Bachelor of Surgery in this University. 2. Of having attended, subsequently to having taken the degree of Bachelor of Surgery in this University: (*a*) to Clinical or Practical Surgery during two years in a hospital or medical institution recognised by this University; or (*b*) to Clinical or Practical Surgery during one year in a hospital or medical institution recognised by this University, and of having been engaged during three years in the practice of his profession; or (*c*) of having been engaged during five years in the practice of his profession, either before or after taking the degree of Bachelor of Surgery in this University. One year of attendance on Clinical or Practical Surgery, or two years of practice, will be dispensed with in the case of those candidates who at the B.S. Examination have been placed in the first division. 3. Of moral character, signed by two persons of respectability. The examination is conducted by means of printed papers and *viva-voce* interrogation, and the subjects are Mental Physiology, especially in its relations to mental disorder, and Surgery. Any candidate for the degree of M.S. may transmit to the Registrar, not later than Oct. 1st a printed Dissertation, Thesis, or Commentary, written in view of candidature, or published within two academical years immediately preceding, treating scientifically some special department of Surgical Science, and showing evidence of his own work or generally tending to the advancement of surgical science; and if the Thesis be approved by the examiners the candidate will be exempt from the written examination in Surgery. The fee is £5.

Doctor of Medicine.—The examination for this degree takes place once in each year, and commences on the first Monday in December. Candidates may present themselves for examination either in Medicine or State Medicine. With regard to the latter, candidates presenting themselves for the M.D. Examination in Medicine must produce certificates to the following effect:—1. Of having attended subsequently to having taken the degree of Bachelor of Medicine in this University: (*a*) to Clinical or Practical Medicine during two years in a hospital or medical institution recognised by this University; (*b*) or to Clinical or Practical Medicine during one year in a hospital or medical institution recognised by this University, and of having been engaged during three years in the practice of profession; (*c*) or of having been engaged during five years in the practice of their profession, either before or after taking the degree of Bachelor of Medicine in this University. 2. Of moral character, signed by two persons of respectability. One year of attendance on Clinical or Practical Medicine or two years of practice will be dispensed with in the case of those candidates who at the M.B. Examination have been placed in the First Division. The examination is conducted by means of printed papers and *viva voce* interrogation, and the subjects are Medicine (or State Medicine), Mental Physiology. Any candidate for the degree of M.D. may transmit to the Registrar, not later than Oct. 1st, a printed Thesis, written in view of candidature, or published within two academical years immediately preceding, treating scientifically some special department of Medical Science and showing evidence of his own work or generally tending to the advancement of Medical Science; and if the Thesis be approved by the examiners the candidate will be exempt from the written examination in Medicine. Fee for the degree, £5.

UNIVERSITY OF DURHAM.

One Diploma and six degrees are conferred—Diploma in Public Health and the degrees of Bachelor of Medicine, Bachelor in Surgery, Master in Surgery, Bachelor in Medicine, Bachelor in Hygiene, and Doctor in Medicine. These degrees are open both to Men and Women.

For the degree of *Bachelor in Medicine* (*M.B.*) four professional examinations.

The subjects of the First Examination are—Human Anatomy and Elementary Biology, Chemistry, and

The subjects for the Second Examination are—Physiology, Materia Medica, Therapeutics, Pharmacy.

The subjects for the Third Examination are—Surgery, Pathology, Medical Jurisprudence, Public Midwifery and Diseases of Women and Children.

The subjects of the Fourth Examination are Medicine, Clinical Surgery, Psychological Medicine.

N.B.—It is required that at least one of the of professional education shall be spent in at the University College of Medicine, Newcastle. Candidates for the First Examination who have First Examination of the Conjoint Board in candidates who hold a qualification from Licensing Body in the United Kingdom, will from the First Examination of the University the subjects of Chemistry and Physics. Ca

Digitized by Google

have passed the First and Second Examinations of the University will be exempt from First and Second Examinations of the Conjoint Board.

For the degree of *Bachelor in Surgery (B.S.)* every candidate must have passed the examination for the degree of Bachelor in Medicine of the University of Durham, and must have attended one course of lectures on Operative Surgery, and one course on Regional Anatomy. Candidates will be required to perform operations on the dead body, and to give proof of practical knowledge of the use of surgical instruments and appliances.

For the degree of *Master in Surgery (M.S.)* candidates must not be less than twenty-four years of age, and must satisfy the University as to their knowledge of Greek. In case they shall not have passed in this subject at the Preliminary Examination in Arts for the M.B. degree they must present themselves at Durham for examination in it at one of the ordinary examinations held for this purpose before they can proceed to the higher degree of M.S. They must also have obtained the degree of Bachelor in Surgery of the University of Durham, and must have been engaged for at least two years, subsequently to the date of acquirement of the degree of Bachelor in Surgery, in attendance on the practice of a recognised hospital, or in the naval or military services, or in medical or surgical practice.

The subjects of examination are:—Principles and Practice of Surgery, Surgical Pathology, Surgical Anatomy, Surgical Operations, Clinical Surgery.

For the degree of *Doctor in Medicine (M.D.)* candidates must be not less than twenty-four years of age, and must satisfy the University as to their knowledge of Greek. In case they shall not have passed in this subject at the Preliminary Examination in Arts for the M.B. degree, they must present themselves at Durham for examination in it at one of the ordinary examinations held for this purpose before they can proceed to the higher degree of M.D. They must also have obtained the degree of Bachelor in Medicine of the University of Durham, and must have been engaged for at least two years, subsequently to the date of acquirement of the degree of Bachelor in Medicine, in attendance on the practice of a recognised hospital, or in the military or naval services, or in medical and surgical practice. Each candidate must write an Essay, based on original research or observation, on some medical subject selected by himself, and approved of by the Professor of Medicine, and must pass an examination thereon, and must be prepared to answer questions on the other subjects of his curriculum so far as they are related to the subject of the Essay.

The University of Durham has instituted a special examination whereby the degree of Doctor of Medicine may be obtained without residence. Candidates shall not be under forty years of age and shall have been in active practice for fifteen years as registered medical practitioners. They shall produce certificates of moral character from three registered members of the medical profession, and if they have not passed an examination in Arts previously to the Professional Examination in virtue of which they have been placed on the Register, they shall be required to pass in Classics and Mathematics. They will be examined in the Principles and Practice of Medicine, including Psychological Medicine, Hygiene, and Therapeutics, the Principles and Practice of Surgery, Midwifery, and Diseases of Women and Children, Pathology (Medical and Surgical), Anatomy (Medical and Surgical), Medical Jurisprudence, and Toxicology. The fee will be fifty guineas, of which twenty guineas will be returned if the candidate fails to satisfy the examiners. Examinations in accordance with the above regulations will be commenced in September, 1895, and will be continued in April and September, 1896, at the College of Medicine, Newcastle-upon-Tyne.

For the degree of *Bachelor in Hygiene (B.Hy.)* and *Doctor in Hygiene (D.Hy.)* see Public Health, p. 643.

Candidates for any of the above degrees must give at least twenty-eight days' notice to the Professor of Anatomy, College of Medicine, Newcastle-upon-Tyne.

VICTORIA UNIVERSITY.

Colleges of the University: Owens College, Manchester; University College, Liverpool; and Yorkshire College, Leeds.

Matriculation, which consists in signing the University Register, must precede entry upon any course of study in a College of the University, if that course is to be counted towards the required minimum of attendance for a degree. Those only can matriculate who are registered students of a College of the University.

Four degrees in Medicine and Surgery are conferred by the Victoria University—viz., Bachelor of Medicine and Bachelor of Surgery (M.B. and Ch.B.), Doctor of Medicine (M.D.), and Master of Surgery (Ch.M.).

All candidates for degrees in Medicine and Surgery are required to pass an examination called the Entrance Examination in Arts, or to have passed such other examination as may be recognised by the University for this purpose.[4]

Degrees of Bachelor of Medicine and Bachelor of Surgery.—Before admission to the degree of M.B. or Ch.B. candidates are required to present certificates that they will have attained the age of twenty-one years on the day of graduation, and that they have pursued the courses of study required by the University Regulations during a period of not less than five years subsequently to the date of their registration by the General Medical Council, two of such years having been passed in a College of the University, and one year at least having been passed in a College of the University subsequently to the date of passing the First M.B. Examination. All candidates for the degrees of Bachelor of Medicine and Bachelor of Surgery are required to satisfy the examiners in the several subjects of the following examinations: the First Examination, the Second Examination, and the Final Examination.

The First Examination.—The subjects of examination are as follows:—(1) Chemistry; (2) Elementary Biology; (3) Physics. Candidates must have attended during at least one year courses both of lectures and of laboratory work in each of the above-named subjects. The Examination is divided into two parts: Part 1, Physics and Chemistry; Part 2, Biology; and the candidates may pass in these parts separately.

The Second Examination.—The subjects of examination are as follows:—A: (1) Anatomy; (2) Physiology, including Physiological Chemistry and Histology; B: (3) Materia Medica and Pharmacy. Candidates may pass in A or B separately. Candidates presenting themselves in A alone, or in B alone, and failing to satisfy the examiners, must present themselves again in the same subjects or in A and B together.

The Final Examination.—The subjects of examination are as follows:—(1) Pharmacology and Therapeutics. (2) General Pathology and Morbid Anatomy. (3) Forensic Medicine and Toxicology, and Public Health. (4) Obstetrics and Diseases of Women. (5) Surgery, Systematic, Clinical and Practical. (6) Medicine, Systematic and Clinical, including Mental Diseases and Diseases of Children.

Candidates may either present themselves in all the six subjects of examination on the same occasion, or may pass the examination in two parts, the first part consisting of *two* or *three* of the subjects (1), (2) and (3), the second part of the remaining subjects.

Candidates who fail to satisfy the examiners in a first part must either present themselves again in the subjects as selected or in all the six subjects of examination.

Candidates for the First Part of the examination must have completed the *fourth winter* of medical study, in accordance with the regulations of the University.

Candidates for the Second Part of the examination, or for the whole examination, must have completed the fifth year of medical study, in accordance with the regulations of the University.

Degree of Doctor of Medicine.—Candidates are not eligible for the degree of Doctor of Medicine unless they have previously received the degree of Bachelor of Medicine, and at least one year has elapsed since they passed the examination for that degree. Candidates for the degree of Doctor of Medicine are required to present a printed Dissertation embodying the results of personal observations or original research, either in some department of medicine or of some science directly relative to medicine.

[4] The examinations at present recognised are:—1. The Preliminary Examination of the Victoria University, provided Latin and Mechanics have been taken up. 2. The Matriculation Examination of the University of London. 3. The Previous Examination of the University of Cambridge. 4. Responsions of the University of Oxford. 5. The Leaving Certificate Examination of the Oxford and Cambridge Boards, provided that it include Latin, English, Mathematics, and Elementary Mechanics. 6. The Final Examination for Graduation in Arts of any university in Great Britain and Ireland.

Digitized by Google

No candidate will be admitted to the degree unless his Dissertation, after report from the Departmental Board of Medical Studies, shall have been recommended by the General Board of Studies to the Council for acceptance in that behalf. Candidates may be examined on any subject connected with their dissertations.

Degree of Master of Surgery.—Candidates are not eligible for the degree of Master of Surgery unless they have previously received the degree of Bachelor of Medicine, and at least one year has elapsed since they passed the examination for that degree. The subjects of examination are as follows: (1) Surgical Anatomy; (2) Surgical Pathology; (3) Practical Surgery, including the performance of operations on the dead body; (4) Clinical Surgery; (5) Ophthalmology.

UNIVERSITY OF EDINBURGH.

Four Degrees in Medicine and Surgery are conferred by the University of Edinburgh—viz., Bachelor of Medicine (M.B.), Bachelor of Surgery (Ch.B.), Doctor of Medicine (M.D.), and Master of Surgery (Ch.M.). The degree of Bachelor of Surgery shall not be conferred on any person who does not at the same time obtain the degree of Bachelor of Medicine, and the degree of Bachelor of Medicine shall not be conferred on any person who does not at the same time obtain the degree of Bachelor of Surgery.

Subject to regulations to be made from time to time by the University Court, the University may also confer diplomas in special branches of medical and surgical practice on graduates of the University in Medicine and Surgery.

Before commencing his medical studies each student must pass a preliminary examination in (1) English, (2) Latin, (3) Elementary Mathematics, and (4) Greek or French or German: Provided always that, in the case of a candidate whose native language is not English, an examination in the native language of the candidate may be substituted for one in either French or German, and an examination in any other classical language for one in Latin or Greek.

No one is admitted to the degrees of Bachelor of Medicine and Master in Surgery who has not been engaged in Medical and Surgical study for five years. No course of lectures will be allowed to qualify unless the lecturer certifies that it has embraced at least one hundred lectures, or fifty lectures, in conformity with the requirements of this section. Three months' courses on Materia Medica, Pathology, and Midwifery do not qualify.

Candidates for the degrees of M.B. and C.M. must have attended for at least three years the medical and surgical practice either of the Royal Infirmary, Edinburgh, or of a general hospital elsewhere which accommodates not fewer than eighty patients and possesses a distinct staff of physicians and surgeons. They must have attended Clinical Surgery during a course or courses extending over not less than nine months. These courses may be conducted by the professor of clinical surgery, or by professors or lecturers appointed for the purpose by the University Court, or by the ordinary surgeons of the Royal Infirmary, Edinburgh, or of a general hospital defined and recognised as hereinbefore provided, and shall consist of regular instruction at the bedside, along with clinical lectures. A similar course of clinical medicine during a course or courses extending over not less than nine months is required. The candidate must have attended a course of instruction in Mental Diseases of such duration, and so apportioned between lectures, demonstrations, and clinical instruction, as the Senatus, with the approval of the University Court, may from time to time determine. The candidate must have attended a course of twenty-five meetings on Practical Pharmacy in a university or recognised school of medicine, or have dispensed drugs for a period of three months in a hospital or dispensary, or in an establishment recognised by the Pharmaceutical Society. The candidate must have attended, for at least six months, by apprenticeship or otherwise, the out-practice of a hospital, or the practice of a dispensary, or of a physician or surgeon, or of a member of the London or Dublin Society of Apothecaries. He must have acted as clerk in the medical wards and dresser in the surgical wards of a public hospital; and must also have availed himself, to such an extent as may be required by the Senatus, with the approval of the University Court, of opportunities of studying at a hospital or dispensary. Post-mortem Examinations, Fevers Diseases of Children, Ophthalmology, or such other special departments as may from time to time be determined. The candidate must have attended, under the superintendence of a registered medical practitioner, twelve cases of labour or such additional number as the Senatus, with the sanction of the University Court, may from time to time determine or have attended for three months the practice of a lying in hospital, or of the maternity department of a general hospital or other public charitable institution, and have conducted personally six or such an additional number of cases of labour as the Senatus, with the approval of the University Court, may from time to time determine. The candidate must have been properly instructed in Vaccination at a public vaccination station, by a public vaccinator, authorised by the proper Government authority to grant certificates of proficiency in vaccination.

Next, with respect to the places and institutions at which the studies of the candidate may be prosecuted, the following regulations have effect:—Two of the five years of medical study must be spent in the University of Edinburgh. The remaining three years may be spent in any university in the United Kingdom, or in any Indian, Colonial, or Foreign university recognised for the purpose by the University Court or in such medical schools or under such teachers as may be recognised for the purpose by the University Court. Of the subjects of study, sixteen in number—viz. Anatomy, Practical Anatomy, Chemistry, Practical Chemistry, Materia Medica, Physiology, Practical Physiology, Practice of Medicine, Surgery, Midwifery, Diseases of Women, Pathology and Practical Physiology, Physics, Botany, Zoology, and Medical Jurisprudence—not less than eight must be taken in the University of Edinburgh or in some other university of the United Kingdom, or in such Foreign or Colonial university entitled to confer the degree of Doctor of Medicine, recognised for the purpose by the University Court, or in a college incorporated with, or affiliated to, a university entitled to confer the degree of Doctor of Medicine, recognised for the purpose by the University Court.

Each candidate is examined, both in writing and orally and clinically where the nature of the subject admits, at First, in Chemistry, Zoology, Botany, and Physics; second in Anatomy, Physiology, Materia Medica, and Therapeutics; third, in Pathology, Medical Jurisprudence, and Public Health; and fourth, in Surgery, Medicine, Midwifery, and clinically in Medicine and Surgery in a hospital. The examinations are conducted, as far as possible, by demonstrations of objects placed before the candidates. Candidates who profess themselves ready to submit to an examination in the first division of these subjects may be admitted to examination therein at the first period of examination after they have completed their attendance on the necessary classes. Candidates who have passed their examination in the first division of these subjects may be admitted to examination in the second division at the end of their first year. Candidates who have passed their examination in the subjects comprised in the first and second divisions may be admitted to examination in the third division at the end of the fourth winter session. Candidates who have passed their examinations in the subjects comprised in the first, second, and third divisions may be admitted to examination in the fourth or final division when they have completed the fifth year of study.

Regarding the Professional Examinations for the degrees of M.B. and Ch.B., and also for the degree of M.D. and Ch.M., the conditions are similar to those which hold for the Glasgow University degrees. The fee to be paid for the degrees of Bachelor of Medicine and Bachelor of Surgery is £23 2*s*., and the proportion of this sum to be paid by a candidate at each division of the examination shall be regulated from time to time by the University Court. The fee to be paid for the degree of Doctor of Medicine is £10 10*s*., exclusive of any stamp duty which for the time may be exigible. The fee to be paid for the degree of Master of Surgery is £10 10*s*.

UNIVERSITY OF GLASGOW.

The University of Glasgow is both a teaching and examining body, but only candidates whose course conforms to Glasgow regulations can be admitted to examination. Within certain limits provision is made for accepting instruction given by recognised medical schools and teachers, but eight of the subjects other than clinical must be taken in this or some other recognised university

Digitized by Google

to confer the degree of M.D., and at least two years of the course must be taken in Glasgow University. Under the new regulations four degrees, open both to men and women, are conferred: M.B. and Ch.B. (always conjointly), M.D. and Ch.M. A Preliminary Examination must be passed in (1) English, (2) Latin, (3) Elementary Mathematics, and (4) Greek, or French, or German, with possible options to students whose native language is not English in the case of the fourth subject, and on passing the Preliminary Examination candidates must register as medical students in the books of the General Medical Council. For the degrees of M.B. and Ch.B. a curriculum of five years is required, in each of the first four of which the student must attend at least two five months' courses, or alternatively one five months' course and two courses of two and a half months. The minimum of attendance in the first four years includes five months' courses in the following subjects:—Anatomy, Practical Anatomy (two courses), Chemistry, Materia Medica and Therapeutics, Physiology, Practice of Medicine, Surgery, Midwifery, and Diseases of Women and Infants, and Pathology; and courses of two and a half months in the following:—Practical Chemistry, Physics, Botany, Zoology, Practical Physiology, Practical Pathology, Medical Jurisprudence and Public Health. Candidates must attend at least three years the Medical and Surgical Practice of a recognised hospital accommodating at least eighty patients and having a distinct staff of physicians and surgeons. At least nine months' hospital attendance is required on both Clinical Surgery and Clinical Medicine, and the student must have acted as clerk in medical and dresser in surgical wards, and must have had six months' out-door practice; he must also have attended a course of Mental Diseases and of Practical Midwifery (twenty-five meetings), must have been properly instructed in Vaccination at a public vaccination station, and must have attended at least twelve cases of labour, or three months of the practice of a Lying-in Hospital, six cases being personally conducted. The University is also empowered to require further study in Post-Mortem Examinations, Fevers, Diseases of Children, Ophthalmology, and other special subjects. A candidate may be exempted from attendance and examination in Botany, Zoology, Physics and Chemistry, if he holds a degree in Science or Arts embracing these subjects granted by a British or other recognised university.

There are four Professional Examinations, the first comprising Botany, Zoology, Physics, and Chemistry, to be taken after the completion of the included courses (candidates being at liberty to take two subjects at a time); the second comprising Anatomy, Physiology, and Materia Medica and Therapeutics, to be taken at the end of the third winter session; the third comprising Pathology, Medical Jurisprudence and Public Health, to be taken at the end of the fourth winter session; and the fourth or final, comprising Surgery, Clinical Surgery, Practice of Medicine, Clinical Medicine, and Midwifery, to be taken on completion of the fifth year of study.

The degrees of M.D. (Doctor of Medicine) and Ch.M. (Master of Surgery) are higher degrees in Medicine and Surgery respectively, and candidates (not under twenty-four years of age) who have previously obtained the double bachelorship may be admitted to either M.D. or Ch.M. on completing the after course prescribed, including an examination in Clinical Medicine for M.D. and an examination in Surgical Anatomy, operations on the dead body, and Clinical Surgery for Ch.M.

Fees.—The fees for M.B. and Ch.B. are £23 2*s*. The class fee in each subject of the curriculum for M.B. and Ch.B. is £3 3*s*. and the present fees for hospital attendance are £21. The fee for M.D. is £10 10*s*. (stamp duty being now abolished), and for Ch.M. £10 10*s*. There is a course of instruction (fee £10 10*s*.) and an examination (fee £5 5*s*.) leading to a diploma in Public Health.

The great majority of the students take their hospital course at the Western Infirmary, where clinical instruction is given by professors of the University and other physicians and surgeons. Clinical instruction on Fevers is given at Belvidere Hospital, while special courses, largely of a practical nature and embracing work in Hospital or Asylum wards, are conducted by University Lecturers on the Eye, the Ear, the Throat and Nose, and Insanity. Queen Margaret College, hitherto conducted as a separate institution for the higher education of women, has now been made over to the University, and in it medical classes for women are conducted under University professors and other lecturers appointed by the University Court, whilst for clinical instruction female students are admitted to the Royal Infirmary.

Bursaries and Prizes to the annual amount of about £820 are appropriated to medical students, and Scholarships and Fellowships to the annual amount of about £1600 may be held by medical students who have gone through the Arts course.

In the ordinary course graduations under the regulations for the curriculum of five years introduced in 1892 will begin in July, 1897. Thus far students have been graduating as M.B. and C.M. on a four years' curriculum under the old regulations, and such graduates may afterwards proceed to the degree of M.D. by Thesis after passing a somewhat more stringent preliminary examination, including Greek. Supplementary regulations recently passed by the Scottish Universities Commissioners allow those holding the degrees of M.B. and C.M. under the former regulations to proceed to the new M.D. by Examination and Thesis in the same manner as those who obtain the double Bachelorship under the new regulations. Candidates electing to proceed in this way will be freed from the preliminary examination in Greek, which probably has hitherto deferred many of them from coming forward.

UNIVERSITY OF ABERDEEN.

The curricula for the several degrees conferred are nearly the same as in the Universities of Edinburgh and Glasgow.

Professional Examinations will be held twice in each year—namely, in March and July, directly after the close of the winter and summer sessions.

The fees for graduation are the same as in the University of Edinburgh. Matriculation fee, including all dues, for the winter and summer sessions, £1 1*s*.; summer session alone, 10*s*. 6*d*.

Besides the Royal Infirmary, students have the opportunity of attending the following institutions: General Fever Hospital; Sick Children's Hospital; General Dispensary, and Lying-in and Vaccine Institutions daily; Royal Lunatic Asylum; Eye Institution, in which is given clinical instruction on Diseases of the Eye, and on the application of the Ophthalmoscope for their diagnosis.

A diploma in Public Health is granted by the University to graduates in Medicine of a University in the United Kingdom only, after a special examination. The diploma can be entered on the Register of the General Medical Council.

Application for further information should be addressed to the Secretary of the Medical Faculty.

The degrees of B.Sc. and D.Sc. are granted, after examination, in departments of Science, to be selected by the candidate. For regulations apply to the Secretary of Science Faculty.

UNIVERSITY OF ST. ANDREWS.

Under the existing regulations two degrees in Medicine are granted—namely, Bachelor of Medicine joined with Master in Surgery (M.B., C.M.), and Doctor of Medicine (M.D.). New regulations have, however, been prepared, but are not yet in force. They will provide for the conferring of four degrees—viz., Bachelor of Medicine (M.B.), Bachelor of Surgery (Ch.B.), Doctor of Medicine (M.D.), and Master of Surgery (Ch.M.). The curricula and examinations for these degrees will be nearly the same as in the Universities of Edinburgh and Glasgow. It will be a condition that two of the five years of study must be spent in the University of St. Andrews.

The degree of *Doctor of Medicine* may be conferred by the University of St. Andrews on any registered medical practitioner above the age of forty years whose professional position and experience are such as, in the estimation of the University, to entitle him to that degree, and who shall, on examination, satisfy the medical examiners of the sufficiency of his professional knowledge; provided always that degrees will not be conferred under this section on a greater number than ten in any one year. The examinations are held yearly about the end of March. Candidates must lodge with the Dean of the Medical Faculty the following certificates, along with application for admission to examination:—1. A certificate of age, being a baptismal certificate or an affidavit. 2. Holograph certificates from at least three medical men of acknowledged reputation in the medical profession or

Digitized by Google

in the medical schools, recommending the candidate to the Senatus for the degree and testifying to his professional skill and position. 3. A portion of the graduation fee (viz., £10 10*s*.), which shall be forfeited should the candidate fail to appear at the time appointed for examination or fail to graduate. A satisfactory examination, written and *viva voce*, must be passed in the following departments — viz., Materia Medica and General Therapeutics, Medical Jurisprudence, Practice of Medicine and Pathology, Surgery, Midwifery and Diseases of Women and Children.[5]

No one will be received as a candidate for the degree of *Bachelor of Medicine and Master in Surgery* unless two years at least of his four years of medical and surgical study shall have been passed in one or more of the following universities or colleges—viz., the Universities of St. Andrews, Glasgow, Aberdeen, Edinburgh, Oxford, or Cambridge; Trinity College, Dublin; Queen's College, Belfast; Queen's College, Cork; and Queen's College, Galway.

Subject to the condition here specified, the studies for candidates for the degrees of Bachelor of Medicine and Master in Surgery will be under the following regulations: The remaining years of medical and surgical study may be either in one or more of the universities and colleges above specified, or in the hospital schools of London, or in the school of the College of Surgeons of Dublin, or under such private teachers of medicine as may from time to time receive recognition from the University Court. Attendance during at least six winter months on the Medical or Surgical practice of a general hospital which accommodates at least eighty patients, and during the same period on a course of Practical Anatomy, may be reckoned as one of such remaining years.

Every candidate for examination for the degree of M.B. and C.M. is required to lodge a declaration of age, a statement of his course of study, his inaugural dissertation, and all his certificates with the Dean of the Medical Faculty on or before the 25th of February in each year.

UNIVERSITY OF DUBLIN (TRINITY COLLEGE).

Matriculation.—All students in the School of Physic intending to practise Physic must be matriculated, for which a fee of 5*s*. is payable. No student can be admitted for the winter course after Nov. 25th.

Degrees in Medicine (M.B.), Surgery (B.Ch.), and Midwifery (B.A.O.).—Candidates for these degrees must be of B.A. standing and must be for at least five academic years on the books of the Medical School, reckoned from the date of matriculation. The Arts course may be concurrent with the medical course, and the B.A. degree need not be taken before the final medical examination, but the medical degrees are not conferred without the Arts degree. The following courses must be attended:—(1) Lectures — Systematic, Practical and Applied Anatomy, Chemistry and Practical Chemistry, Surgery and Operative Surgery, Histology, Botany, Zoology, Physics, Physiology, Practice of Medicine, Midwifery, Pathology, Materia Medica and Therapeutics, Medical Jurisprudence and Hygiene; (2) three courses of nine months' attendance in the Clinical Lectures of Sir Patrick Dun's or other recognised Dublin Hospital, one year at a recognised London or Edinburgh hospital before the commencement of the Dublin curriculum being counted as one year spent in such Dublin hospital; (3) Practical Vaccination, one month's instruction; (4) Mental Disease, three months'; (5) Practical Midwifery with Clinical Lectures, including not less than thirty cases, six months'; (6) Ophthalmic Surgery, three months'. Two examinations have to be passed. The Previous Medical or Half M.B. Examination, including Physics and Chemistry, Botany and Zoology, Anatomy and Institutes of Medicine (Practical Histology and Physiology), may be passed when credit has been obtained for the corresponding subjects, and these may be taken separately if desired. The Final Examination is subdivided into five sections, comprising Applied Anatomy (Medical and Surgical), Applied Physiology, Jurisprudence and Hygiene, Materia Medica and Therapeutics, Medicine, Surgery, Pathology, Midwifery, Gynæcology, Obstetrical Anatomy, Clinical Medicine, Mental Diseases, Clinical Surgery, Operations, Clinical Ophthalmology. The first seven of these subjects may be passed in the fourth year and the last eight in the fifth year. Fee for the *Liceat ad Examinandum*, £10. Fee for the degree, £17.

Doctor in Medicine.—A Doctor in Medicine must be M.B. of at least three years' standing, or have been qualified to take the degree of M.B. for three years, and must read a thesis or undergo an examination before the Regius Professor of Physic, in accordance with the rules and statutes of the University. Total amount of fees for this degree, £13.

Master in Surgery.—A Master in Surgery must be a Bachelor in Surgery of the University of Dublin of not less than three years' standing, and must produce satisfactory evidence of having been engaged for not less than two years from the date of his registration in the study, or study and practice of his profession. He must then pass an examination in the following subjects:—1. Clinical Surgery. 2. Operative Surgery. 3. Surgical Pathology. 4. Surgery. 5. Surgical Anatomy (on the dead subject), and one of the following optional subjects:—1. Surgery in one of the following branches—viz., Ophthalmic and Aural, Gynæcological, and Dental. 2. Mental Disease. 3. Medical Jurisprudence and Hygiene. 4. Advanced Anatomy and Physiology. 5. Comparative Anatomy. Fee for the degree of Master in Surgery, £11.

Master in Obstetric Science.—A Master in Obstetric Science must have passed the M.B. and B.Ch. examinations, and produce a certificate of having attended a summer course in Obstetric Medicine and Surgery.[6] He is then required to pass an examination in the following subjects:—1. Practice of Midwifery. 2 Gynæcology. 3. Anatomy of Female Pelvis and Elementary Embryology. 4. Clinical Gynæcology. Fee for the degree of Master in Obstetric Science, £5.

University Diplomas.—Candidates for the diplomas in Medicine, Surgery, or Obstetric Science must be matriculated in Medicine, and must have completed two years in Arts and five years in Medical Studies. The Course and Examination necessary for the diplomas are the same as for the degrees, except that the candidate is not required to attend the Lectures on Botany and Zoology, nor to pass the Previous Medical examination in those subjects. A diplomate on completing his course in Arts and proceeding to the degree of B.A., may become a Bachelor by attending the Lectures on Botany and Zoology, passing the Previous Medical examination in those subjects, and paying the degree fees. Fee for the *Liceat ad Examinandum*, £10. Fee for the diploma in Medicine, £11.

[5] These regulations are still in force; but a new Ordinance is waiting the sanction of the Queen which will considerably alter them. Under it there will be no examination for practitioners.

[6] Existing graduates in Medicine of the standing of M. required to attend this course.

ROYAL UNIVERSITY OF IRELAND.

All Degrees, Honours, Exhibitions, Prizes and Scholarships in this University are open to students of either sex.

Candidates for any degree in this University must have passed the Matriculation Examination. Students from other universities and colleges are included in this rule.

The following degrees, &c., are conferred by the University in this Faculty:—Bachelor of Medicine, Doctor of Medicine, Bachelor of Surgery, Master of Surgery, Bachelor of Obstetrics, Master of Obstetrics; in Sanitary Science, a special diploma; in Mental Disease, a special diploma.

The Medical Examinations, except that for the diploma in Sanitary Science, will be held twice yearly—viz., in June and in October. The examination for the diploma in Sanitary Science will be held in July.

The course for degrees in Medicine, &c., is of at least five years' duration.

The First Examination in Medicine.—Students may be admitted to this examination until the lapse of two academical years from the time of their matriculation. They must also have previously passed the First University Examination. The subjects of this examination are Natural Philosophy, Theoretic Chemistry, Zoology and Botany. The examination in each subject will comprise two parts: 1. A written examination. 2. Practical work and oral examination. For Chemistry the practical examination takes place at the close of the second year. Particular weight will be given to the practical part of the examination. Candidates at the First Examination in Medicine who at the First University Examination in Arts did not obtain 30 per cent. of the marks assigned to French or German will be required to present themselves for a qualifying examination in French or German. Failure to obtain 30 per cent. of the marks assigned to either of those languages will involve the failure in the examination.

Digitized by Google

The Second Examination in Medicine.—Students will be admitted to this examination after the lapse of one academical year from the time of passing the First Examination in Medicine, provided they have completed the first period of the course of medical studies. The subjects for this examination are Anatomy, Physiology, and Practical Chemistry.

The Third Examination in Medicine.—Students will be admitted to this examination after the lapse of one academical year from the time of passing the Second Examination in Medicine, provided they have completed the third year of medical studies. The subjects for this examination will be Anatomy, Physiology, and Materia Medica (Pharmacology).

The Examination for the Medical Degrees.—Students will be admitted to this examination after the lapse of two academical years from the time of passing the Third Examination in Medicine, provided they have completed the course of medical studies prescribed for the fourth year. The examination consists of three parts or divisions:—(*a*) Medicine, including Therapeutics and Pathology, Mental Diseases, Medical Jurisprudence and Hygiene. (*b*) Surgery, Theoretical, Clinical, Operative; Surgical Anatomy, with Ophthalmology and Otology. (*c*) Midwifery and Gynæcology, with Diseases of Children. Each part of this examination must be passed as a whole. Upon completing satisfactorily his examination in all three divisions the candidate will, in addition to the parchment diplomas recording his admission to the Medical Degrees of M.B., B.Ch., and B A.O., receive a certificate of having passed a qualifying examination in the subjects of Medicine, Surgery, and Midwifery. The fee for this certificate is £10, which must be paid prior to the candidate's admission to the Medical Degrees.

M.D. Degree.—Candidates may be admitted to this degree after the lapse of three academical years from the time of obtaining the degree of M.B. Every candidate will be examined at the bedside, and required to diagnose at least three medical cases, and prescribe treatment, and to write detailed reports on at least two cases to be selected by the examiners and to discuss all the questions arising thereon.

The M.Ch. Degree.—This degree will be conferred only on graduates in Medicine of the University of at least three years' standing. The examination for this degree will comprise Surgical Diseases and Surgery, both theoretical and operative; Surgical Anatomy; Ophthalmology and Otology; and will include—(*a*) a written examination; (*b*) a clinical examination; (*c*) an examination on Surgical Instruments and Appliances; and (*d*) an examination in Operative Surgery.

The Mastership in Obstetrics.—This degree will be conferred only on graduates in Medicine of the University of at least three years' standing. The examination will comprise the Theory and Practice of Midwifery and of Diseases of Women and Children and the Use of Instruments and Appliances and will include—(*a*) a written examination; (*b*) a clinical examination as far as practicable; (*c*) an oral examination, with practical illustrations; (*d*) an examination on Instruments and Appliances.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGE OF PHYSICIANS OF LONDON AND THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.[7]

Regulations relating to the several Examinations applicable to Candidates who commenced their Professional Education on or after Jan. 1st, 1892.

Any candidate who desires to obtain both the licence of the Royal College of Physicians of London and the diploma of Member of the Royal College of Surgeons of England is required to comply with the following regulations and to pass the examinations hereinafter set forth.

Professional Examinations.—There are four Examinations, called herein the First Examination, the Second Examination, the Third Examination, and the Final Examination, each being partly written, partly oral, and partly practical. These examinations will be held in the months of January, April, July, and October, unless otherwise appointed. Every candidate intending to present himself for examination is required to give notice in writing to Mr. F. G. Hallett, Secretary of the Examining Board, Examination Hall, Victoria Embankment, W.C., fourteen clear days before the day on which the examination commences, transmitting at the same time the required certificates.

The subjects of the First Examination are—Chemistry and Physics, Practical Pharmacy, Elementary Biology, and Elementary Anatomy. A candidate may take this examination in four parts at different times. A candidate will be admitted to examination in Chemistry and Physics and Elementary Biology before registration as a medical student, and to examination in Practical Pharmacy on producing evidence of having been registered as a medical student by the General Medical Council, *or he may take Pharmacy as part of the Third Examination;* but he will not be admitted to the examination on Elementary Anatomy earlier than the end of his first winter session at a medical school or than the completion of his first six months' attendance at a recognised medical school during the ordinary sessions—i.e. exclusively of the months of April, August, and September. A candidate rejected in one part or more of the First Examination will not be admitted to re-examination until after the lapse of a period of not less than three months from the date of rejection, and he will be re-examined in the subject or subjects in which he has been rejected. If referred in Chemistry, Biology, or Elementary Anatomy, he must produce evidence of further instruction. Any candidate who shall produce satisfactory evidence of having passed an examination for a degree in Medicine on any of the subjects of this examination conducted at a university in the United Kingdom, in India, or in a British colony will be exempt from examination in those subjects in which he has passed.

The fees for admission to the First Examination are as follows: For the whole examination, £10 10*s.*; for re-examination after rejection in Part I. £3 3*s.*, and for re-examination in each of the other parts, £2 2*s.*

The subjects of the Second Examination are Anatomy and Physiology. Candidates will be required to pass in both subjects at one and the same time. Candidates will be admissible to the Second Examination at the expiration of two winter sessions and one summer session (or fifteen months during the ordinary sessions) from the date of registration as Medical Students and after the lapse of not less than six months from the date of passing Parts I., III., and IV. of the First Examination.

A candidate referred on the Second Examination will be required, before being admitted to re-examination, to produce a certificate that he has pursued, to the satisfaction of his teachers, in a recognised place of study, his Anatomical and Physiological studies during a period of not less than three months subsequently to the date of his reference.

The fees for admission to the Second Examination are: £10 10*s.* for the whole examination, and £6 6*s.* for re-examination after rejection.

The subjects of the Third Examination are: Part I. Medicine, including Medical Anatomy, Pathology, Practical Pharmacy, Pharmacology, Therapeutics, Forensic Medicine, and Public Health. Candidates who have passed in Practical Pharmacy at the First Examination will not be re-examined in that subject at the Third Examination. Part II. Surgery, including Pathology, Surgical Anatomy, and Apparatus. Part III. Midwifery and Diseases peculiar to Women. Candidates may present themselves for examination in Midwifery and Diseases of Women at the Third Examination or at the Final Examination. Candidates may take this examination in three parts at different times, or they may present themselves for the whole examination at one time. They will be required to produce the following evidence before being admitted to any part of the Third, or of the Final Examination—viz., of having studied Medicine, Surgery, and Midwifery; and the following Special Certificates before being admitted to the respective parts of the examination—viz., in Medicine, of having attended Practical Instruction in Medicine, Lectures on Pathology, Clinical Lectures on Medicine during nine months, and of having discharged the duties of Medical Clinical Clerk; in Surgery, of having attended Practical Instruction in Surgery, Lectures on Pathology, of having performed operations upon the Dead Subject, Clinical Lectures on Surgery during nine months, and of having discharged the duties of Surgical Dresser; in Midwifery of having attended Practical Instruction in Midwifery, Clinical or other Lectures, with Practical Instruction in Diseases Peculiar to Women, and of attendance on 20 Labours.

Fees for admission to the Third Examination with or

[7] The diploma of Member of the Royal College of Surgeons of England and the Licence of the Royal College of Physicians of London are no longer granted separately except to students who commenced their professional study prior to Oct. 1st, 1884.

Digitized by Google

without Midwifery and Diseases peculiar to Women, are as follows: For the whole examination £10 10*s*. Part I. For re-examination in Medicine, including Medical Anatomy, Pathology, Therapeutics and Public Health, £3 3*s*.; for re-examination in Pharmacology, £1 1*s*.; for re-examination in Practical Pharmacy (if taken at this examination) £3 2*s*. Part II. For re-examination in Surgery, including Pathology, Surgical Anatomy and Apparatus, £3 3*s*. Part III. For re-examination in Midwifery and Diseases peculiar to Women, £3 3*s*.

The Final Examination shall consist of (1) Clinical Medicine, (2) Clinical Surgery, and (3) Midwifery and Diseases peculiar to Women. Candidates may present themselves for examination in Midwifery and Diseases peculiar to Women at the Third Examination or at the Final Examination. The examination in Parts I. and II. consists of Written Papers and *viva voce* on Patients. Candidates who have passed the Third Examination will be admissible to the Final Examination on production of the required certificates of study at the expiration of five years' (five winter and five summer sessions) study from the date of registration as medical students and at the expiration of twelve months from the date of passing the Third Examination. Candidates will be required to present themselves for examination in Clinical Medicine and Clinical Surgery together. No candidate will be allowed to pass in one without obtaining at the same time at least half the number of marks required to pass in the other. A candidate referred on the Final Examination will not be admitted to re-examination until after the lapse of a period of not less than three months from the date of rejection and will be required, before being admitted to re-examination, to produce a certificate, in regard to Medicine and Surgery, of having attended the Medical and Surgical Practice, or the Medical or Surgical Practice, as the case may be, during the period of his reference; and, in regard to Midwifery and Diseases peculiar to Women, a certificate of having received, subsequently to the date of his reference, not less than three months' instruction in that subject by a recognised teacher.

The fees for admission to the Final Examination are as follows: For the whole Examination, £5 5*s*.; for re-examination after rejection in Clinical Medicine, £2 12*s* 6*d*.; for re-examination after rejection in Clinical Surgery, £2 12*s*. 6*d*.; for re-examination after rejection in Midwifery and Diseases peculiar to Women, £3 3*s*.

ROYAL COLLEGES OF SURGEONS AND PHYSICIANS OF EDINBURGH, AND FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.

These Colleges have made arrangements by which, after one series of examinations, held in Edinburgh or in Glasgow, or in Edinburgh and Glasgow, the student may obtain the diplomas of the three Bodies.

The three Bodies grant their Single Licences only to candidates who already possess another and opposite qualification in Medicine or Surgery, as the case may be, recognised by them. Copies of the Regulations for the Single Licence of any of the Bodies may be had on application to the respective Secretaries.

Professional Education.—1. Candidates who commenced medical study *before* Jan. 1st, 1892, must have been engaged in professional study during forty-five months from the date of registration as medical students by the General Medical Council, which period shall include not less than four winter sessions' attendance at a recognised medical school. 2. The candidate must produce certificates or other satisfactory evidence of having attended the following separate and distinct courses of instruction: Anatomy, during at least six months; Practical Anatomy, twelve months; Chemistry, six months; Practical or Analytical Chemistry, three months; Materia Medica, three months; Physiology, six months; Practice of Medicine, six months; Clinical Medicine, nine months; Principles and Practice of Surgery, six months; Clinical Surgery, nine months; Midwifery and the Diseases of Women and Children, three months; Medical Jurisprudence, three months; Pathological Anatomy, three months. The six months' courses delivered in Scotland must consist of not fewer than 100 lectures. The three months' courses must consist of not fewer than fifty lectures. The number of lectures certified as attended at any school not situated in Scotland should not be less than three-fourths of the total number of lectures delivered in a course. 3. The candidate must also produce the following certificates:—(*a*) Of having attended not less than six cases of labour, three of these to be conducted personally under the direct superintendence of the practitioner who signs the certificate, who must be a registered medical practitioner. (*b*) Of having attended, for three months, instruction in Practical Pharmacy; the certificate to be signed by the teacher, who must be a member of the Pharmaceutical Society of Great Britain, or the superintendent of the laboratory of a public hospital or dispensary, or a registered practitioner who dispenses medicines to his patients, or a teacher of a class of Practical Pharmacy. (*c*) Of having attended for twenty-four months the Medical and Surgical practice of a public general hospital containing on an average at least eighty patients available for Clinical instruction and possessing distinct staffs of physicians and of surgeons. (*d*) Of having attended for six months (or three months, with three months' hospital clerkship) the practice of a public dispensary specially recognised by any of the above authorities; or the out-patient practice of a recognised general hospital, or of having acted for six months as pupil to a registered practitioner who either holds such a public appointment, or has such opportunities of imparting practical knowledge as shall be satisfactory to the coöperating authorities; this attendance should be made after the student has passed the First and Second Examinations. (*e*) Of having been instructed by a registered medical practitioner in the Theory and Practice of Vaccination, and of having performed operations under the teacher's inspection, during a period of not less than six weeks.

Candidates shall be subjected to three Professional Examinations, and they may enter either for the whole of an Examination or for a division thereof.

First Examination.—The First Examination shall embrace the two divisions of (1) Chemistry,[8] (2) Elementary Anatomy,[9] and Histology,[10] and shall take place not sooner than the end of the first year, including the period of winter and a summer session. For the whole Examination taken at one time the sum of £5 5*s*. must be paid to the inspector of certificates not later than one week preceding it, after which no candidate will be entered. After rejection for re-entry in all subjects, £3 3*s*.; for re-entry after obtaining exemption from re-examination in one or two subjects £2 2*s*.; for entering for one division of subjects separately £3 3*s*.; and for each re-entry after rejection, £2 2*s*. A candidate who shall produce satisfactory evidence of having passed an equivalent examination in any of the subjects of the First Examination before any of the boards specified in the Regulations will be exempt from examination in such subjects.

Second Examination.—The Second Examination shall embrace the three subjects of (1) Anatomy, (2) Physiology, (3) Materia Medica and Pharmacy, each of which shall constitute a division of the examination, and may be entered separately. The examination shall not take place before the termination of the summer session of the second year of study, including two winters and two summers. The fee for admission to this examination, payable not later than one week before the day of examination, are as follows:—For the whole Examination, £5 5*s*.; after rejection for re-entry in all subjects, £3 3*s*.; for re-entry, after obtaining exemption from re-examination in one or two subjects, £2 2*s*.; for entering one subject separately, £2 2*s*.; and for each re-entry after rejection, £2 2*s*. Any candidate who shall produce satisfactory evidence of having passed an equivalent examination in any of the subjects of the Second Examination before any of the boards specified in the Regulations will be exempt from examination in such subject or subjects.

Final Examination.—The Final Examination shall embrace the three divisions of—(1) the Principles and Practice of Medicine (including Therapeutics, Medical Anatomy, Pathology) and Clinical Medicine; (2) the Principles

---

[8] The examination in Chemistry shall embrace the following particulars: Chemical Physics (meaning thereby Heat, Light, Electricity); the principal Non-Metallic and Metallic Elements, and their more common combinations; also the leading Alcohols, Organic Ethers, Carbo-hydrates, and Alkaloids. The candidate will be examined practically in Testing.

[9] Elementary Anatomy shall embrace: Anatomy of the Bones and Joints of the whole body, and of the Muscles, chief Blood-vessels, Nerves of the Upper and Lower Extremities.

[10] Histology shall include a knowledge and recognition of the morphological elements and structure of Skin, Bone, Cartilage, Fibrous Tissue, Hair, Nails, Teeth, Blood, Muscle, Nervous Tissue, the appearance and distribution of all the different forms of Epithelium, along with a general knowledge of the properties of Protoplasm. Examination on this subject will be practical and oral.

Digitized by Google

Practice of Surgery (including Surgical Anatomy and Surgical Pathology) and Clinical Surgery; (3) Midwifery and Gynæcology, Medical Jurisprudence, and Hygiene (which divisions may be entered for separately at different times); and shall not take place before the termination of the full period of study. The fees for this Examination, payable not later than one week before the examination day, are as follows: For the whole Examination, taken at one time, in the case of candidates who have passed the First and Second Examinations, £15 15*s*., of which £10 10*s*. shall be returned to unsuccessful candidates. For entering for each of the three divisions of subjects separately, £6 6*s*., and on re-entry after rejection, £2 2*s*. in respect of each division or part thereof. This rule will also apply to any subsequent rejection. Any candidate admitted to the Final Examination, on the footing of having passed in the subjects of the First and Second Examinations at a recognised board, shall, on entering, pay the full fee of £26 5*s*.

All candidates shall be subjected, in addition to the Written and Oral Examinations, to Clinical Examinations in Medicine and Surgery, which shall include the Examination of Patients, Physical Diagnosis, the Clinical Use of the Microscope, Examination of the Urine and Urinary Deposits, Surgical Appliances, Bandages, Surface Markings, &c.

REGULATIONS FOR CANDIDATES COMMENCING STUDY *after* JANUARY 1ST, 1892.

The curriculum lasts for five years; the fifth year should be devoted to clinical work at one or more public hospitals or dispensaries. Six months of the fifth year may be passed by the student as a pupil to a registered practitioner possessing such opportunities of imparting practical knowledge as may be deemed satisfactory by the Committee of Management. The student's regularity of attendance in the wards and out-patient departments of the hospitals and at the post-mortem examinations should be duly ascertained and noted on the certificate.

Candidates shall be subjected to four Professional Examinations:

First Examination.—The First Examination shall embrace the following divisions of subjects—(1) Physics, (2) Chemistry, and (3) Elementary Biology. The fees payable for admission to the First Examination shall be for the whole Examination, £5; for each division separately, £2 10*s*.

Second Examination.—The Second Examination shall embrace Anatomy and Physiology including Histology; and candidates may be admitted to this Examination at the end of the second year of medical study. The fees payable for admission to the Second Examination shall be—for the whole Examination, £5.

Third Examination.—The Third Examination shall embrace Pathology, Materia Medica and Pharmacy. The fees payable for admission to the Third Examination shall be—for the whole Examination, £5; for re-entry in both subjects after rejection, £3.

Final Examination.—The Final Examination shall not be passed earlier than the end of the fifth year of study, and shall embrace the following divisions of subjects:—(1) Medicine, including Therapeutics, Medical Anatomy, and Clinical Medicine; (2) Surgery, including Surgical Anatomy, Clinical Surgery, and Diseases and Injuries of the Eye; (3) Midwifery and Diseases of Women and of New-born Children; and (4) Medical Jurisprudence and Hygiene. All candidates shall be subjected, in addition to the Written and Oral Examinations, to Clinical Examinations in Medicine and Surgery, which shall include the Examination of Patients, Physical Diagnosis, the Clinical use of the Microscope, Examination of the Urine and Urinary Deposits, Surgical Appliances, Bandages, Surface markings, &c. The fees payable for the Final Examination shall be,—for the whole Examination, £15, for re-entry in all subjects after rejection, £5; on entering for each division of subjects separately, £6, on re-entry in each division after rejection, £2.

There are six periods of Examination annually, four in Edinburgh and two in Glasgow, and candidates may present themselves at either examining centre irrespective of the place of the previous examination. The Registrar in Edinburgh is Mr. J. Robertson, 1, George-square; and the Registrar in Glasgow, Mr. A. Duncan, 242, St. Vincent-street, to whom fees and certificates must be sent.

Note.—In applying for copies of the Regulations students should state whether they commenced medical study before or after Jan. 1st, 1892.

ROYAL COLLEGE OF PHYSICIANS AND ROYAL COLLEGE OF SURGEONS IN IRELAND.

Two sets of Regulations are at present in force, under which examinations take place for the conjoint diploma of these bodies. The older Regulations, under which students who commenced their studies before Dec. 31st, 1891, may be examined, have appeared in our Student's Number in previous years, and will be found on pp. 477 and 478 of our second volume of 1888. The following Regulations are obligatory on all students commencing on or after the date already mentioned:—

PRELIMINARY EXAMINATION AND REGISTRATION.

Every candidate for the Conjoint Examinations of the Colleges shall produce evidence—(*a*) of having, before entering on medical studies, passed a Preliminary Examination in general education recognised by the General Medical Council; and (*b*) of having been registered by that Council as a Student in Medicine. Each candidate before receiving his diplomas must produce a registrar's certificate or other satisfactory evidence that he has attained the age of twenty-one years.

Preliminary Examination.—The subjects for examination are identical with those prescribed for the Preliminary Examination by the General Council of Medical Education and Registration.

PROFESSIONAL EXAMINATIONS.

Every candidate is required to pass four Professional Examinations—at the end of the first, second, fourth and fifth years of his professional studies. No candidate shall be admitted to the Final or Qualifying Examination within three months of his rejection at the Final or Qualifying Examination by any other licensing body. All examinations shall be conducted as far as possible by demonstration of objects placed before the candidates.

First Professional Examination.—Every candidate is required, before admission to the First Professional Examination, to produce evidence—(1) of having passed in the subjects of the Preliminary Examination; (2) of having been registered as a medical student by the General Medical Council; and (3) of having attended a course of—(*a*) Demonstrations and Dissections, (*b*) lectures on Theoretical Chemistry, winter courses; (*c*) Practical Chemistry, three months' summer or winter course; (*d*) Elementary Biology; (*e*) Physics. [*Note.*—Biology and Physics may be studied either before or after registration at institutions recognised for the purpose by the Colleges.] (*f*) Practical Pharmacy—(1) evidence of attendance for three months in the compounding department of a clinical hospital, which hospital shall have satisfied the committee of management that its means of instruction are sufficient, and shall return to the committee the names of its students at the commencement of the course, together with a record of their attendance at its close; or (2) evidence of attendance on a course of Practical Pharmacy in a recognised medical school, the course to consist of not less than twenty demonstrations; or (3) evidence of having served a full apprenticeship of three years, or of having acted as paid assistant for not less than one year, in the establishment of a Licentiate apothecary or of a registered pharmaceutical chemist. The fee for this examination is £15 15*s*.

The subjects of the First Professional Examination are the following:—1. (*a*) Chemistry; (*b*) Physics. 2. Practical Pharmacy. 3. Elementary Biology. 4. Anatomy—viz., Bones, with attachments of Muscles and Ligaments, and Joints. Candidates may take this examination as a whole at one time or in four parts, but no portion earlier than the end of the first winter session.

Second Professional Examination.—Candidates are not admissible to this examination before the end of their second winter session. Every candidate is required, before admission to the Second Professional Examination, to produce evidence of having passed the First Professional Examination; also certificates of having attended—(1) a medico-chirurgical hospital for nine months; (2) Demonstrations and Dissections for six months; (3) Practical Histology for three months; (4) Lectures on (*a*) Anatomy for six months; (*b*) Physiology for six months; (*c*) Materia Medica for three months. Materia Medica may be deferred to the third year. The fee for this examination is £10 10*s*.

The subjects of the Second Professional Examination are the following:—1. Anatomy: the anatomy of the whole human body; (2) Histology; (3) Human Physiology;

Digitized by Google

(4) Materia Medica. The candidate must present himself, in the first instance at least, in Anatomy, and Histology; if he pass in either of these subjects he may, at the discretion of the examiners, get credit therefor. Physiology and Materia Medica may, at the option of the candidate, be passed at the end of the second or during the third year.

Third Professional Examination.—Candidates are not admitted to this examination before the end of their fourth winter session. Every candidate is required, before admission to the Third Professional Examination, to produce evidence of having passed the Second Professional Examination; also, in addition to the certificates required for the Second Professional Examination, certificates of having attended—(1) a medico-chirurgical hospital for eighteen months; (2) a midwifery hospital or maternity, including evidence of having been present at thirty labours;[11] for six months; (3) clinical instruction in Mental Diseases at an institution recognised by the Colleges[11] for three months; (4) Operative Surgery, including operations on the Dead Subject, not less than thirty meetings of the class; (5) Demonstrations and Dissections, for six months; (6) Vaccination;[11] (7) Practical Pathology, not less than thirty meetings of the class; (8) Lectures on (*a*) Medicine for six months; (*b*) Surgery for six months; (*c*) Public Health and Forensic Medicine for three months; (*d*) Midwifery, including Diseases peculiar to Women and to New-born Children, for six months. Nos. 2, 3, and 6 may be deferred to fifth year. Satisfactory evidence must be produced of attendance in fever wards in connexion with the hospital attendance in either the third or a subsequent year. The fee for this examination is £9 9*s*.

The subjects for the Third Professional Examination are the following:—(1) Medicine; (2) Surgery; (3) Pathology; (4) Therapeutics; (5) Public Health and Forensic Medicine. A candidate must present himself, in the first instance at least, in Medicine, Surgery, and Pathology. Should he pass in either Medicine or Surgery he shall get credit therefor, even if he have failed in other parts of the examination.

Final Professional Examination.—Candidates are not admissible to this examination before the end of their fifth year of medical study. Every candidate is required before admission to produce evidence—(1) of having passed the Third Professional Examination; (2) of having attended—(*a*) Clinical Instruction in Ophthalmic and Aural Surgery for three months; (*b*) a midwifery hospital or maternity, if not taken in the fourth year, for six months; (*c*) Vaccination, if not taken in the third or fourth year; (*d*) Clinical Instruction in Mental Diseases, if not taken in the fourth year.

The subjects for the Fourth Professional Examination are the following:—(1) Medicine, including Medical Anatomy and Mental Diseases; (2) Surgery; (3) Operative Surgery and Surgical Anatomy; (4) Ophthalmic and Aural Surgery; (5) Midwifery, including Diseases of Women and New-born Children; and (6) the Theory and Practice of Vaccination. Every candidate shall produce evidence of having acted as medical clinical clerk and as surgical dresser. The fee for this examination is £6 6*s*.

SOCIETY OF APOTHECARIES OF LONDON.

There are three examinations, Primary, Intermediate, and Final. The Primary Examination is held quarterly, on the first Wednesday and on the Monday and Thursday of the same week, in the months of January, April, July, and October. The Intermediate and Final Examinations are held monthly.

The Primary Examination consists of two parts. Part I. includes Elementary Biology; Chemistry, the Principles of the Science which bear on the Study of Medicine; Chemical Physics, including the Elementary Mechanics of Solids and Fluids, Heat, Light, and Electricity; Practical Chemistry; and Pharmacy. A synopsis indicating the range of the subjects in the examination will be sent with the regulations on application. Evidence of instruction in these subjects must be produced prior to examination. Part II. includes Anatomy, Physiology, and Histology. This examination cannot be passed before the completion of twelve months Practical Anatomy with Demonstrations, and these subjects cannot be taken separately except in the event of the candidate having previously passed in one. Evidence must be produced of the candidate's course of study. A schedule for the Primary Examination, to be obtained of the Secretary, must be signed by the Dean of the Medical School or other authority. The Intermediate Examination consists of three parts. Part I. includes the Principles and Practice of Surgery, Surgical Pathology, and Surgical Anatomy. Part II. includes the Principles and Practice of Medicine, together with Therapeutics, Pharmacology, and Prescriptions; Pathology and Morbid Histology; Forensic Medicine, Hygiene, Theory and Practice of Vaccination; and Mental Diseases. Part III. includes Midwifery, Gynæcology, and Diseases of New-born Children and the Use of Obstetric Instruments and Appliances. Part III. may be postponed to the Final Examination, and candidates may enter for Parts I., II., and III. together or separately. The Intermediate Examination cannot be passed before the expiration of forty-five months after registration as medical student, during which time not less than three winter sessions and two summer sessions must have been passed at one or more of the medical schools connected with a general hospital recognised by the Court of Examiners. The Final Examination consists of three Parts. Part I. includes an Examination of and Written Report on Surgical Cases, and Operative Manipulation and Surgical Anatomy, Instruments and Appliances. Part II. includes an Examination of and Written Report on Medical Cases and Medical Anatomy. Part III. includes Midwifery, Gynæcology, and Diseases of New-born Children, and the Use of Obstetric Instruments and Appliances. Parts I. and II. of this examination cannot be passed before the end of the fifth year.

The course of study for the Primary Examination is as follows:—Elementary Biology, not less than three months; Chemistry and Chemical Physics, six months; Practical Chemistry, three months; Pharmacy and Dispensing, three months; Anatomy, six months; Practical Anatomy with Demonstrations, twelve months; Physiology six months; Histology with Demonstrations, three months. The study of these subjects must be pursued at a Medical School or at a place of instruction recognised by the Society. Evidence of having received instruction in Biology and Chemistry before registration as medical student will be admitted. Instruction in Pharmacy and Dispensing must be given by a registered medical practitioner or by a member of the Pharmaceutical Society by examination or in a public hospital, infirmary, or dispensary.

The course of study for the Intermediate Examination includes attendance on the Surgical and Medical Practice (with Post-mortem Examinations) at a hospital connected with a medical school for a period of three winter and two summer sessions; lectures on the Principles and Practice of Surgery, six months; Practical Surgery, three months; Clinical Surgical Lectures, nine months; Dressership,[12] six months. Performance of Surgical Operations on the Dead Body; lectures on Principles and Practice of Medicine, six months; Pathology, three months; Clinical Medical Lectures, nine months; Clinical Clerkship,[12] six months; Forensic Medicine, Hygiene, and Insanity, three months; Midwifery and Gynæcology, three months; Clinical Instruction in the same, three months; a course of Practical Midwifery; attendance on twenty Midwifery cases. The course of medical study must extend over the above-mentioned period of forty-five months.

The course of study for the Final Examination includes either attendance on the Practice of Medicine and Surgery at a hospital or other institution recognised by the Society for a further period of twelve months, or six months as above and six months as a pupil of a registered practitioner holding a public medical or surgical appointment, or attendance at the special hospitals for six months (three months at each hospital), and for six months at a general hospital, all such hospitals to be recognised by the Society. Evidence shall also be given of practical instruction in Infectious Diseases and in Mental Diseases (at a lunatic asylum or in the wards of an institution containing a special ward set apart for the treatment of mental diseases), and in any two of the following subjects: Ophthalmic Surgery, Laryngology with Rhinology and Otology, Dermatology, Diseases of Children. These courses may be taken at a general hospital recognised by the Society any time after the student has held the post of Dresser and Clinical Clerk. No candidate is eligible for

[11] May be taken in either the fourth or fifth year.

[12] These offices may be held at a hospital, infirmary, or dispensary where sufficient opportunities are afforded for the acquirement of practical knowledge.

Digitized by Google

Final Examination who has not completed the curriculum prescribed by the Society, in evidence of which a schedule, to be obtained of the Secretary, must be produced, signed by the Dean of the Medical School or other authority. Prior to the Final Examination the candidate must produce certificates: (1) of being twenty-one years of age; (2) of moral character; (3) of the course of medical study; and (4) of proficiency in vaccination signed by a teacher authorised by the Local Government Board. Candidates intending to present themselves for examination are required to give fourteen days' notice. A form for this purpose will be sent on application.

The fee for the three examinations is 15 guineas, or 5 guineas for each examination, except in the case of persons holding a foreign diploma, who are required to pay the entire fee of 15 guineas. The Secretary to the Examiners attends at the Hall of the Society, Blackfriars, E.C., from 10 to 12 o'clock daily.

ROYAL COLLEGE OF SURGEONS IN IRELAND AND THE APOTHECARIES' HALL OF IRELAND.[13]

Every candidate for the Conjoint Diplomas of the Royal College of Surgeons and Apothecaries' Hall must produce evidence—(*a*) of having, before entering on medical studies, passed a Preliminary Examination in General Education recognised by the General Medical Council; and (*b*) of having been registered by that Council as a Student in Medicine. Certificates of medical study will not be recognised if the commencement of the course to which the certificate refers dates more than fifteen days prior to such registration. This registration is not undertaken by the corporations; but the student must apply to the Medical Registrar, 35, Dawson-street, Dublin, in order that he may be so entered. No fee is payable for registration. Every candidate for the Conjoint Diplomas is required to pass a Preliminary Examination as prescribed by the Medical Council and four Professional Examinations. Mechanics and Physics will in future form a portion of the first year's professional study. All examinations in general education recognised by the General Medical Council are accepted by the College of Surgeons and Apothecaries' Hall.

Sessional Medical Examinations.—The Examinations will be held in January, April, July, and October of each year, unless otherwise appointed by the committee of management, beginning with the First Examination.

First Examination.—Candidates are required, before admission to the First Professional Examination, to produce evidence: 1. Of having been registered by the Medical Council as medical students at least six months before examination. 2. Of having attended (*a*) Demonstrations and Dissections, (*b*) Chemistry, (*c*) Physics (winter courses, six months), (*d*) Practical Chemistry, (*e*) Biology (summer courses, three months), (*f*) Practical Pharmacy for three months in the Compounding Department of a Clinical Hospital or a School of Pharmacy, or in the Compounding Establishment of a Licentiate Apothecary. A candidate may take this examination as a whole at one time or in four parts, but the examination in Anatomy not earlier than the end of his first winter session. Fee for First Examination, £5 5*s.*[14]

Second Examination.—Candidates must produce evidence of having passed the First Professional Examination; also certificates of having subsequently attended—(*a*)[15] a Medico-Chirurgical Hospital and of having taken notes of at least three Medical cases and three Surgical cases, or a certificate of Clinical Clerkship; (*b*) the following courses of Lectures: (1) Practical Anatomy; (2) Demonstrations and Dissections; (3) Physiology (winter courses, six months); (4) Materia Medica (or in third year); (5) Practical Histology (summer courses, three months).

Third Examination.—Candidates must produce evidence of having passed the Second Examination; also certificates of having subsequently attended—(*a*)[15] a Medico-Chirurgical Hospital, and notes of at least three Medical and three Surgical cases, or of having acted as Clinical Clerk; (*b*) the following courses of Lectures: (1) Medicine; (2) Surgery (winter courses); (3) Public Health and Forensic Medicine together; (4) Practical Pathology—Laboratory Course, at least thirty meetings of class (summer course). Fee for third examination, £5 5*s.*

Final Examination.—The candidate must produce evidence—(1) of having passed the Third Professional Examination; (2) of having subsequently attended—(*a*)[15] a Medico-Chirurgical Hospital for nine months as extern pupil, or six months as resident pupil; (*b*) Lectures on Midwifery (a winter course); (*c*) a recognised Midwifery Hospital, or Maternity (or in fifth year), for six months, with evidence of having been present at thirty labours; (*d*) Clinical Instruction in Mental Diseases at an institution recognised by the College and Hall (may be taken in either fourth or fifth year); (*e*) Operative Surgery, including operations on the dead subject, at least thirty meetings of the class; of three months' study of Fever in a Clinical Hospital containing fever wards, and of having taken notes of at least five cases of fever; (*f*) Clinical Instruction in Ophthalmic and Aural Surgery (three months); (*g*) Vaccination. *Note.*—Attendance at a Fever Hospital will not be recognised if concurrent with that on Practical Midwifery.

[12] By agreement between the Corporations this conjoint scheme was closed for new entries on June 30th, 1895. Students who entered before that date are allowed to complete their examinations.

[14] Reduction of examination fees: The total fees for the diplomas of L.R.C.S.I. and L.A.H. will in future be £26 5*s.*—i.e., £5 5*s.* for each of the first three examinations and £10 10*s.* for the final. Candidates who commenced study under any previous scheme to this will be entitled to credit for the fees which they have already paid to either the College of Surgeons or the Apothecaries' Hall, as against the amount of the fees for the respective examinations as above stated; but in case they have not passed with either body previous examinations under this scheme they must pay the fees which would have accrued to that body if they had done so.

[15] The student is required to attend a Medico-Chirurgical Hospital for twenty-seven months, to be distributed, at his own discretion, over the last four years of his study.

UNIVERSITY OF BRUSSELS.

British and other practitioners holding registrable qualifications are admissible for the Doctorate of the University of Brussels without any further curriculum. It is necessary, however, that all candidates should leave their diplomas with the Registrar of the University prior to the examination, and no one will be admitted until this condition has been complied with. The fees are—For matriculation, £8 12*s.*; for 1st Doctorate, £4 8*s.*; for 2nd Doctorate, £4 4*s.*; for 3rd Doctorate, £4 8*s.*; for legalisation of diploma, 8*s.*—£22. The unsuccessful candidates may present themselves again three months after rejection. Candidates who have paid in advance the fees for the three examinations, and are unsuccessful in the first, recover the fees paid for the second and third; those who fail in the second recover the fees paid for the third examination. There are three examinations, viz.—1st Doctorate: Medicine, Special and General Pathology and Pathological Anatomy with the Microscope; General Therapeutics; Materia Medica and Pharmacology; Mental Diseases; Diseases of Women. 2nd Doctorate: Surgery; Midwifery; Hygiene; Medical Jurisprudence. 3rd Doctorate: Clinical Examination in Medicine at the Hospital; Clinical Surgical Examination; Examination in Midwifery, consisting in obstetrical operations on the mannikin (model of pelvis); Examination in Operative Surgery, consisting in some of the usual operations on the dead subject, such as Amputation, Ligature of an Artery, &c.; Regional Anatomy on the Dead Body, with Dissections; Ophthalmology. Great importance is attached to practical knowledge, but candidates must also prove that they possess positive theoretical science. The examinations, which are *vivâ voce*, take place on the first Tuesday in November, December, February, May, and June. Candidates have the option of passing each Doctorate separately or of taking the three at one examination. The time required for the three examinations seldom exceeds ten days. Saturday, before 2 P.M., is the most eligible day for arriving for candidates with whom time is an object. The examinations are conducted in English. There are in England at present about 600 graduates holding this degree, and an English Association of Brussels Graduates has been formed.

All applications concerning the examination should be made to Dr. Albert Mills, 30, Rue du Pépin, Brussels, or to Mr. Walter Reeve, 28, Victoria-street, Westminster, between the hours of 4 and 5, except Mondays and Saturdays.

THE ARMY, NAVY, AND INDIAN MEDICAL SERVICES.

Consequent upon the issue of the Royal Warrant of August, 1891, alterations have taken place in the designations of the departmental rank of the officers of the Army Medical

Digitized by Google

Staff, and medical officers are also now placed, as regards sick leave of absence on full pay, on the same footing as those laid down for regimental officers. By a subsequent Royal Warrant, dated Nov. 10th, 1891, Art. 1208 of the Pay Warrant was revised by inserting the words "an officer of our Medical Staff" after the words "combatant officer," thus giving medical officers an equal title with combatant officers to reckon time on half-pay towards retirement, when the half-pay has been due to ill-health contracted in the performance of military duty. The substantive ranks of officers of the Medical Staff carry precedence and other advantages attaching to the rank indicated by the military portion of it, with such exceptions and within such limits as are laid down in the earlier Warrant.

In the *Gazette* of Aug. 25th, 1891, it was announced that the Queen had been pleased, by Royal Warrant, dated Aug. 7th, 1891, to approve of the following alterations of the designations of the departmental rank of the officers of the Medical Staff now serving as follows:—Surgeons-General, ranking as Majors-General, to be Surgeons-Major-General; Deputy Surgeons-General, ranking as Colonels, to be Surgeons-Colonel; Brigade-Surgeons, ranking as Lieutenant-Colonels, to be Brigade Surgeons-Lieutenant-Colonel; Surgeons-Major, ranking as Lieutenant-Colonels, to be Surgeons-Lieutenant-Colonel; Surgeons-Major, ranking as Majors, to be Surgeons-Major; Surgeons, ranking as Captains, to be Surgeons-Captain. The rank of the Director-General of the Army Medical Department is that of Surgeon-Major-General.

[For the text of the Warrant of Aug. 7th for the Medical Staff, *vide* THE LANCET of Aug. 22nd, 1891, page 459 *et seq.*]

Admission into the Army and Indian Medical Services is gained as the result of competitive examination. Under special conditions the admission may take place by nomination of the Secretary of State for War. Candidates for both services must, before being admitted to examination, possess a double qualification to practise Medicine and Surgery, and be registered under the Medical Act. They are also now required to produce certificates of having acted as a medical clinical clerk for six months, as surgical dresser for another six months, and of having had not less than three months' instruction at an ophthalmic hospital or the ophthalmic department of a general hospital, including a course on errors of refraction. They must also furnish satisfactory certificates of moral character. A candidate for the Army must be between the ages of twenty-one and twenty eight, in good mental and bodily health, and must sign a declaration upon honour that he is of pure European descent; for the Indian Service a candidate must be between twenty-one and twenty-eight, of sound bodily health, and a natural-born subject of Her Majesty. Both are examined as to physical fitness by a Board of Medical Officers. These conditions being satisfied, the candidate is admitted to the competitive examination, which is usually held in London twice a year, in the months of February and August. An entrance fee of £1 is payable at the conclusion of the candidate's physical examination, if he be pronounced fit. No candidate for either Service will be allowed to compete on more than two occasions. The subjects of examination are divided into *compulsory* and *voluntary*. The former comprise Anatomy and Physiology, Surgery, Medicine, including Therapeutics and the Diseases of Women and Children, Chemistry and Pharmacy, and a practical knowledge of Drugs. The eligibility of the candidate for admission into the service is determined by the result of this part of the examination. By an Army Order dated May 1st, 1895, no candidate shall be considered eligible who shall not have obtained at least one-third of the marks obtainable in each of the compulsory subjects, and at least one-half of the aggregate of marks for all the compulsory subjects. The *voluntary* subjects are French, German, Comparative Anatomy, Zoology, Natural Philosophy, Physical Geography, and Botany, with especial reference to Materia Medica, and for the Indian service Hindustani. Although the results of the examination in voluntary subjects do not affect the question of the eligibility of the candidate for a commission, they influence his position on the list, which is determined by the numbers obtained under the two heads conjointly. After having passed this examination, the successful candidates for both services are sent to the Army Medical School at Netley as "surgeons on probation," receiving a daily pay of 8*s.* and certain allowances, to go through a four months' course of instruction in the special duties required of them in the service. The staff of the school consists of four professors, all of them men of high standing in their special departments. The Professorship of Military Medicine is held by Deputy Surgeon General Henry Cayley, I.M.S. Brigade-Surgeon-Lieutenant-Colonel W. F. Stevenson, M.S., is Professor of Military Surgery; Brigade-Surgeon-Lieutenant-Colonel J. L. Notter, M.D., of Military Hygiene; and Dr. A. E. Wright, of Pathology. To each of these an Army Medical Officer is attached as Assistant Professor. The lectures on Military Surgery include gunshot and other wounds, transport of sick and wounded, duties of army medical officers in the field, on board troopships and transports, recruiting, and other duties incident to military service. Those on Military Medicine treat of tropical and other diseases to which soldiers are exposed in the course of their service, the mortality and invaliding by disease, in peace and war, at home and abroad, the management of lunatics under the conditions of military service, &c. The course of six lectures on Lunacy and Military Asylum work is delivered at the Netley Lunatic Asylum by Surgeon-Lieutenant-Colonel Irving. The course of Hygiene comprises the examination of water and air, the general principles of diet, with the quality and adulterations of food and beverages, the sanitary requirements of barracks, hospitals, and camps, the clothing, duties, and exercises of the soldier, and the circumstances affecting his health, with the best means of preventing disease, and instruction in the mode of preparing the various statistical and other returns required of the medical officer. The Pathological course includes bacteriology and demonstrations in Physiological chemistry. The surgeons on probation are detailed for duty in the wards of the hospital, under the Professors and Assistant Professors of Medicine and Surgery. They spend two months in the medical and two months in the surgical division of the hospital, and there they are taught practically the details of the management of patients in a military hospital, the registration of their diseases, the duties of invaliding, the modes of filling up the regulation statistical returns and other service documents. The surgeons on probation are provided with quarters and are extra members of the mess at Netley. After having passed through the course of instruction they are examined on the subjects taught in the school, and their position on the list of those recommended for commissions is determined by the combined results of the competitive and final examinations. At the close of each session eight prizes are awarded: the Herbert Prize of £20 to the surgeon on probation who has obtained the highest number of marks at the Netley examination; the Parkes Memorial Bronze Medal to the one who gains the highest number of marks in the examination in Hygiene; the De Chaumont prize of books to the one who takes second place in Hygiene; the Martin Memorial Gold Medal for the highest number of marks in the examination on Military Medicine: the Montefiore Medal and £21, awarded for Military Surgery; the Montefiore Second Prize a cheque for the purchase of surgical or scientific instruments, to the surgeon on probation who obtains the second highest number of marks in this branch; the Maclean prize of books for Clinical Medicine and Surgery and for Ward Work; and a prize of books for the highest number of marks gained in Pathology.

At the close of the Netley Session those surgeons on probation who have obtained one-third of the possible total of marks in each subject are recommended for commissions as Surgeon Lieutenants. The Surgeon-Lieutenants of the British Medical Service pass on from Netley to Aldershot, where they go through a systematic course of instruction in ambulance drill and equitation. The surgeons of the Indian Medical Service do not go to Aldershot, but undergo, whilst at Netley, a course of instruction in company and ambulance drill and in other military duties.

The Army Medical Staff.—Surgeon-Lieutenants, if recommended by the Director-General, Army Medical Department, are promoted to be Surgeon-Captains on completing three years' full-pay service.

Surgeon-Captains, if recommended by the Director-General, are promoted to be Surgeon-Majors on completing twelve years' full-pay service, of which three must have been passed abroad. Before being promoted they will be required to pass an examination. This examination may be taken at any time after their seventh year of service. It will embrace the following subjects: *a*. Surgery and Surgical Anatomy. *b*. Medicine and Pathology.

Digitized by Google

c. Hygiene, within the limits treated of in "Parkes' Practical Hygiene"; also the regulations regarding the sanitation of garrisons, quarters, hospitals, &c., as well as of camps and hospitals in the field, and of transports, troop and hospital ships. *d.* Duties of medical officers at home and abroad and at sea, as defined in the regulations; also hospital organisation and administration in peace and war, including the transport of sick and wounded by land and sea. *e.* The administration, interior economy, command, and discipline of the Medical Staff Corps, together with a knowledge of the principles of military law and their practical application (a certificate of proficiency in military law obtained at a garrison class will exempt the holder from examination in the latter).

A certificate will be required from a recognised teacher of surgery in any medical school, at home or abroad, in which operative surgery is taught, showing that the medical officer has gone satisfactorily through a complete course of operative surgery during the period within which the examination must be taken, and that he is a competent operator.

A report on any subject of a practical professional character, to be selected by the officer himself, and certified to be his own composition and in his own handwriting, will also be required. Considerable importance will be attached to the literary and scientific merits of this report.

The examinations will be conducted by printed questions, which will enter so far into the subject matter of each head selected for examination as to show that the officer's knowledge has been fully tested.

The questions and answers will be forwarded, under a sealed confidential cover, to the Director-General for transmission to the examiners, who will report to the Director-General as to the competence of the officer examined.

The examination in Medicine and Surgery will be held by two gentlemen appointed by the Secretary of State; that in Hygiene by the Professor of Hygiene, Army Medical School, Netley; and that in Regulations, Duties, Military Law, *&c.* by an administrative medical officer, nominated for the purpose by the Director-General.

Any higher qualification, such as M.D., F.R.C.S. &c., or any diploma in Hygiene and State Medicine, taken after May 1st, 1890, will not exempt Surgeon-Captains from this examination.

Surgeon-Majors are, if recommended by the Director-General, Army Medical Department, promoted to be Surgeon-Lieutenant-Colonels on completing twenty years' full-pay service.

The selection of Surgeon-Lieutenant-Colonels for advancement to the grade of Brigade-Surgeon-Lieutenant-Colonel is made on the grounds of ability and merit, in determining which the following points will be considered:—The officer to be so selected must have been favourably reported on by the several military and departmental officers under whom he may have served, as set forth in their Annual Confidential reports. He must be physically fit for general service and have the necessary qualifying foreign and Indian service under existing rules.

A Brigade-Surgeon-Lieutenant-Colonel, to be eligible for selection as Surgeon-Colonel, must have served abroad at least ten years, of which three must have been in India. All officers under the rank of Surgeon-Colonel are placed on the retired list at the age of fifty-five, and those of that rank and of the rank of Surgeon-Major-General at the age of sixty, except that in any particular case in which it may be considered necessary for the interest of the public service the age of retirement of a Surgeon-Major-General may be extended for a period not exceeding two years.

Service on the West Coast of Africa.—Officers who entered the Army Medical Staff, or volunteered expressly for service on the West Coast of Africa on or after the 1st of March 1873 receive double pay while actually serving on the Coast. Candidates who present themselves expressly for service in the Army Medical Staff on the West Coast enter under the same qualifications as other candidates, except that they may be admitted up to 30 years of age. After 3 years' actual service on the coast they are eligible for general service. If, however, it be certified by a medical board that any such officer is unfit for further duty on the coast, he shall be eligible for general service, though he may not have completed 3 years service there. For each year's service on the coast an officer is entitled to a year's leave at home. Each year or portion of a year served on the West Coast reckons double towards voluntary retirement or retired pay, provided that an officer has served 12 months on the coast.

Indian Medical Service.—The alteration of titles of medical officers in the Indian Service, so as to assimilate them to those of the Army Medical Staff, was promulgated in a Royal Warrant dated Dec 7th, 1891. The articles of this Warrant were ordered to take effect from Aug 7th, 1891, the date of the Medical Staff Warrant. By this Warrant the ranks of the medical officers in the Indian military forces were declared to be substantive ranks, and to carry with them the same precedence and other advantages as the corresponding ranks in the Army Medical Staff, including command over the medical officers and subordinates, native and European, engaged in hospital service. The function of military command is subject to the same restrictions as in the British service. An important provision of this Warrant is that Surgeon-Lieutenants "shall be promoted" to the rank of Surgeon-Captain on completing three years' full-pay service, Surgeon-Captains to the rank of Surgeon-Major after twelve years' service, and Surgeon-Majors to the rank of Surgeon-Lieutenant-Colonel after twenty years' service. No examination to qualify for promotion is required. All promotions to higher grades are to be given by selection for ability and merit. In case of distinguished service in the field a medical officer may be at once promoted from any rank to the one next above it. The ages for compulsory retirement are the same as those for the Medical Staff.

Naval Medical Service.—Surgeons are promoted to be Staff Surgeons after twelve years from date of entry, provided they pass the requisite examination; and Staff Surgeons to Fleet Surgeons after twenty years' service if recommended by the Director-General. Deputy-Inspectors-General are promoted by selection from the Fleet Surgeons, and Inspectors-General from the Deputy Inspectors-General having three years' foreign, four years' mixed, of which not less than two must have been abroad, or five years' home service in such appointments as preclude foreign service, provided they have not refused to go abroad when called upon to do so. Inspectors and Deputy Inspectors-General are retired compulsorily at sixty (except that if in any particular case the Lords Commissioners of the Admiralty may consider that the interests of the public service will be materially advanced by the further retention of an Inspector-General on the active list, the age for retirement of such Inspector-General may be extended to sixty-two) and other grades at fifty-five years of age, and all ranks at any time if they have not served for five years. In calculating service for retired pay time on half-pay will be taken as equivalent to one-third service on full-pay.

The following tables, showing the rates of pay and half-pay of the three branches, will probably be acceptable to students who entertain any intention of entering the public service:—

‡ If the health of a surgeon breaks down before he completes eight years' service, even if his disability be contracted in the service or be due to climatic causes, he is liable to be at once placed on the retired list, receiving a gratuity at the rate of £125 for each year of completed service.

INDIAN MEDICAL SERVICE §

The following are the rates of "Indian pay and allowances" which will be drawn by officers hereafter appointed to the Indian Medical Service:—

Rank.	Years' service.	Indian pay and allowances per Mensem. When not holding an appointment carrying higher pay. Rs. a. p.
Brigade-Surgeon-Lieutenant-Colonel and Surgeon-Lieutenant-Colonel ..	25 and over	888 12 0
Surgeon Lieutenant-Colonel	20 ,,	852 3 7
Surgeon-Major	15 ,,	677 6 11
,, ,,	12 ,,	640 14 6

Rank.	Years' service.	A. When not receiving any staff allowance. Rs. a. p.	B. When receiving staff allowance in addition. Rs. a. p.
Surgeon-Captain ..	10 ,,	451 14 5	410 9 5
,, ,, ..	6 ,,	433 10 2	392 5 2
,, ,, ..	5 ,,	335 12 2	304 14 2
Surgeon-Captain and Surgeon-Lieutenant	under 5	317 8 0	286 10 0

On first appointment they will only come into receipt of "Indian pay and allowances" from the date of their arrival in India.

Officers holding the principal administrative appointments and substantive military charges of the Indian Medical Service receive at present the following consolidated salaries:—

	Rs. per Mensem.
Surgeon-Major-General, Bengal ..	2700
,, ,, ,, Madras ..	2500
,, ,, ,, Bombay ..	2500
Surgeon-Colonel .. .. from ..	2250
to	1800
Brigade-Surgeon-Lieutenant-Colonel or Surgeon-Lieutenant-Colonel of 20 years' service and upwards in substantive charge of a native regiment	1000 with Rs. 90, horse allowance in cavalry regiments.
Surgeon-Major under 20 years' service in substantive charge of ditto ..	800 with Rs. 90 ditto.
Surgeon-Captain above 5 years' full-pay service in substantive charge of a native regiment	600 with Rs. 60 ditto.
Surgeon-Captain or Surgeon-Lieutenant under 5 years' ditto in substantive charge of a native regiment	450 with Rs. 60 ditto.

The salaries of other substantive medical appointments in the Civil and Military Departments are consolidated and vary from Rs. 1800 to Rs. 400 per mensem.

Qualified officers of the Medical Service are also eligible for appointments in the Assay Department. The salaries of these appointments are from Rs. 600 to Rs. 2250 per mensem.

Officers are required to perform two years' regimental duty in India before they can be considered eligible for civil employment.

RETIRING PENSIONS AND HALF-PAY.

Officers of the Indian Medical Service will be allowed to retire on the following scale of pension, on completion of the required periods of service:—

	Per annum.
After 30 years' service for pension	£700
,, 25 ,, ,, ,, ...	500
,, 20 ,, ,, ,, ...	365
,, 17 ,, ,, ,, ...	292

Officers not entitled to pension, when placed on temporary or permanent half-pay will be granted the British rate of half-pay of their military rank, as under:—

Rank.	Rates of Half-pay. Per diem.	Per annum.
	s. d.	£ s. d.
Brigade-Surgeon-Lieutenant-Colonel .. Surgeon-Lieutenant-Colonel	11 0	200 15 0
Surgeon-Major	9 6	173 7 6
Surgeon-Captain	7 0	127 15 0
Surgeon-Lieutenant	3 0	54 15 0

§ No staff or regimental allowance can be drawn until the lower standard examination in Hindustani has been passed. As most surgeon-lieutenants have been sent to the frontier immediately on arriving in India, they have found it impossible to study and pass this examination, and have consequently been doing regimental and other work for Rs. 317 8a. a month. Lately a concession has been granted to medical officers so situated on the frontier, but the rule is still most illiberal and requires alteration.

Officers cannot retire *in India* on half-pay (No. 45, Feb. 28th, 1865).

METROPOLITAN MEDICAL SCHOOLS HAVING A COMPLETE CURRICULUM.

ST. BARTHOLOMEW'S HOSPITAL AND COLLEGE.—The clinical practice of the hospital comprises a service of 75 beds, of which 676 are for patients in the hospital at Smithfield and 75 for convalescent patients at Swanley. Ten house physicians and ten house surgeons are appointed annually each of them holding office for one year, and provided with rooms by the hospital authorities. The ophthalmic house surgeon is appointed for six months, and is eligible for re-election for a second term of six months. A midwifery assistant is appointed every six months and an extern midwifery assistant every three months. The senior assistant chloroformist and junior assistant chloroformist are appointed annually, and are provided with rooms. Two qualified assistant electricians are appointed every three months. Each of these officers receives a salary of £ except the chloroformists, who receive £75 and £ respectively, and the extern midwifery assistant, who receives £50 a year. The clinical clerks, the obstetric clerks, the clerks to the medical out-patients, the dressers to the surgical in-patients and to the out-patients and the dressers in the special departments are chosen from the diligent students. All the appointments are now free.

A college is attached to the hospital, in which students can reside, subject to the college regulations.

Foundation and other Prizes.—Two Open Scholarships in Science of the value of £75 each, tenable for one year, will be competed for in September. Candidates must not be more than twenty-five years of age, and must not have entered to the medical or surgical practice of any metropolitan medical school. The subjects of examination

Digitized by Google

Physics and Chemistry for the one, and Physiology and Biology for the other.—Two Junior Open Scholarships, one of £150 and one of £50, in the subjects of the Preliminary Scientific Examination of the London University, will be competed for at the same time. Candidates must be under twenty years of age, and must become regular students.—The Jeaffreson Exhibition, of the value of £20, is awarded at entrance after examination in the subjects of general education. It is now an Open Exhibition.—A Senior Scholarship, £50, in Anatomy, Physiology, and Chemistry.—Kirkes' Scholarship and Gold Medal in Clinical Medicine, value 40 guineas.—Lawrence Scholarship and Gold Medal, of the value of 40 guineas (founded in 1873 by the family of the late Sir William Lawrence).—Two Brackenbury Scholarships in Medicine and Surgery, £30 each.—Four Junior Scholarships in the subjects of study of the first year: 1st, £30; 2nd, £20; 3rd, £25; 4th, £15.

A prize of £15 for Pathological Anatomy has been founded by the late Mr. Henry Skynner in memory of his brother; a Scholarship of £50, confined to Cambridge graduates in Arts, by Miss Shuter, in memory of her brother, formerly assistant surgeon to St. Bartholomew's Hospital; and a prize of £10 10*s* by Sir F. A. Burrows, Bart., in memory of his father, Sir George Burrows.

Research Studentship in Pathology.—In order to encourage young qualified men to engage in research work the treasurer of the hospital appoints annually a student to engage in pathological research. The studentship is of the value of £100 a year.

The Medical School Buildings include three large lecture theatres, a large dissecting room, a spacious library (containing 13 000 volumes), a well-appointed museum of anatomy, physiology, comparative anatomy, materia medica, botany, and pathological anatomy. The Pathological Museum is the largest and most complete of any in the kingdom. There are laboratories for chemistry, physiology, pathology, pharmacology, public health, and biology, giving ample accommodation in every department.

A large recreation ground of ten acres has been purchased by the school committee at Winchmore-hill for the use of the Students' Amalgamated Clubs, and was formally opened last summer.

Instruction in Preliminary Science is given to University of London students in chemistry, biology, and physics throughout the year.

Laboratory Instruction for the D.P.H. is provided during the winter and summer sessions, and elementary instruction in Bacteriology is given throughout the year.

CHARING-CROSS HOSPITAL AND COLLEGE.—Total fees, 110 guineas if paid in a single sum on entry, or 121 guineas if paid in five instalments; the sons of Registered Medical Practitioners pay 100 guineas in one sum or 110 guineas in five sums; for Dental students, 54 guineas, or 60 guineas in two equal instalments. General students pay proportionately lower fees, and are admitted without additional fee to the courses of Clinical Medicine and Surgery and to the practice of the Royal Westminster Ophthalmic Hospital. They alone are entitled to compete for the Scholarships, Gold Medal, and Pereira Prize.

Two Entrance Scholarships, of the value of 120 guineas and 60 guineas respectively, are awarded annually at the commencement of each winter session after a competitive examination in the following groups of subjects:—(1) English, including Language, History, and Geography; (2) Any two of the following four languages—Latin, Greek, French, and German; (3) Mathematics, including Arithmetic, Algebra, and Geometry; and Mechanics, including Statics and Dynamics; (4) Inorganic Chemistry and experimental Physics, including Acoustics, Heat, Magnetism, Electricity, and Optics; and (5) Animal and Vegetable Biology. The value attached to each group of subjects is 1000 marks. 200 marks will be deducted from the number of marks given for each paper, so that no credit will be given for any paper in which the candidate obtains less than one-fifth of the total marks. Candidates must be under 25 years of age on the first day of the Examination. No candidate may offer himself for examination in more than three of the above groups of subjects, the selection of the groups being left entirely to the candidate. Candidates must give notice to the Librarian of their intention to compete, and of the groups in which they offer themselves for examination, on or before Saturday, Sept. 14th, 1895. The examination will commence at the School on Monday, Sept. 16th, at 10 A.M., and will continue during the week. The successful candidates will be required to enter forthwith for their complete medical education at the Charing-cross Hospital. A Universities' Scholarship (of the value of 60 guineas) is open to students from the University of Oxford who have passed the First M.B. Examination, and to students of the University of Cambridge who have passed the Second M.B. Examination, and who have not entered at any London medical school. Subjects: Anatomy and Physiology, including Histology. The examination for this Scholarship, which will be partly practical, will be held at the School on Sept. 16th and 17th. Candidates must give notice to the Librarian of their intention to compete on or before Saturday, Sept. 14th, 1895. The successful candidate will be required to enter forthwith at Charing-cross Hospital for the completion of his curriculum. The Llewellyn Scholarship of £25, for students who have just completed their attendance on lectures; and the Golding Scholarship of £15, for students who have just completed their second year. The Pereira Prize of £5 is open to all general students, and is awarded annually for the best clinical reports. The Governors' Gold Medal is given for excellence in clinical work. Silver or Bronze Medals, or an equivalent in Books, are awarded to the most distinguished students in all classes; and special prizes in the classes of Dental Surgery, Physiology, and Practical Histology.

Classes for the Preliminary Scientific Examination of the University of London are held at this Medical School. The fee for the whole course, which begins in October, is 15 guineas. There are also special classes for the practical work for the Department of Public Health and a course in the subject of Diseases of tropical climates.

Post-graduate Class and Lectures.—Special series of clinical lectures and practical demonstrations, exclusively arranged for the convenience of practitioners and post-graduate students, are given at the hospital by members of the staff throughout the year. Practitioners wishing to join the class can receive any further information as to the dates and subjects by communicating with the Honorary Secretary, Dr. Willcocks, at the Hospital.

ST. GEORGE'S HOSPITAL.—Students may become Perpetual Pupils by payment of £145, or of £150 in four annual instalments. Perpetual pupils are entitled to perpetual admission to lectures and demonstrations as well as to the entire medical and surgical practice of the hospital; they may compete for all prizes and exhibitions, may become clinical clerks during six months and dressers during another six months, or longer if required, without fee, may attend midwifery practice, and may compete for all hospital and school appointments without extra charge. Four house surgeoncies and four house physicianciés, and the salaried offices of obstetric assistant, senior and junior anæsthetists, medical and surgical registrar, curator and assistant curator of the Museum, besides demonstratorships and a number of junior hospital appointments, are open to perpetual pupils. Students not being perpetual pupils are admitted to lectures, demonstrations, and hospital practice on payment of £45 annually for two years and £20 annually for succeeding years. Such students may become Perpetual in their third year if they wish and if their conduct has been satisfactory.

Entrance Scholarships.—£145, open to sons of medical men; two of £50 each, open to all students commencing their medical studies; two of £85 each, open to students who have passed or completed the curriculum for the Oxford First M.B. or Cambridge Second M.B.; and one of £85 open to students of Provincial University Colleges of similar standing.

Prizes.—The William Brown Exhibition of £100 per annum, tenable for two years, open to any perpetual pupil of St. George's who is under twenty-five years of age, and who shall have obtained a diploma or licence entitling him to be registered as a practitioner of medicine or surgery in England within two years previously to the period fixed for the examination (July). The examination is to test the proficiency of the candidate in Medicine, Midwifery, and Surgery, including Ophthalmic Surgery.—The William Brown Exhibition of £40 per annum, tenable for three years, for general fitness for the exercise of the medical profession and for moral conduct, open to perpetual pupils in their third year of study.—Sir Charles Clarke's Prize (interest of £200 Consols) for good conduct and for clinical work rendered in the service of the hospital; the

Webb Prize in Bacteriology, value £30; the Brackenbury Prize in Medicine, value £32; the Brackenbury Prize in Surgery, value £32; the Treasurer's Prize, £10 10s.; the Thompson Medal; the Brodie Prize for Clinical Surgery; the Acland Prize for Clinical Medicine; the Pollock Prize in Physiology; the Henry Charles Johnson Prize in Anatomy; and General Proficiency Prizes, value £10 10s. each, for students of each year.

GUY'S HOSPITAL.—*Appointments:* House physicians, house surgeons, assistant house physicians and assistant house surgeons, obstetric residents, clinical assistants, surgeons' and assistant surgeons' dressers, surgical ward clerks, clinical clerks, post-mortem clerks, extern obstetric attendants, and dressers and clerks in the special departments are appointed from among the students upon the recommendation of the medical staff, according to merit and without extra payment. The house physicians, of whom there are four, hold office for six months each. The assistant house physicians, who hold office for three months, attend in the Out-patient Department four afternoons in the week, and see all the cases not seen by the assistant physician of the day. The house physicians have the care of the patients in the medical wards, and attend to all emergencies arising in the absence of the physicians. They are provided with board and lodging in the college free of expense. The house surgeons, of whom there are four, hold office for six months each, and are provided with board and lodging in the college free of expense. The Surgical Casualty Department is in charge of two assistant house surgeons. The surgeons' dressers are selected from those students who have completed their third winter session, and have been most diligent in the junior appointments. They hold office for three or six months. Six are attached to each surgeon, and during their weeks of special duty they are provided with board and lodging in the hospital free of expense. The obstetric residents, two in number, are provided with board and lodging in the college free of expense

Scholarships, Prizes, &c.—Entrance Scholarships in Arts (£100 and £50). Subjects: Latin, Greek, French, German, and Mathematics.—Entrance Scholarships in Science (£150 and £60). Subjects: Inorganic Chemistry, Zoology, Botany and Physics. The examination begins on Tuesday, Sept. 24th.—First-year students: First prize £50 second prize £25, for Anatomy, Physiology, and Chemistry; the Arthur Durham Prize for Dissection, £5 to first-year students, £15 to those of later years.—For second-year students: First prize £25, second prize £10, for Anatomy, Physiology, and Materia Medica. The Sands Cox Scholarship of £15 (tenable for three years) for Physiology. The Michael Harris prize of £10 for Anatomy.—For third-year students: First prize £25, second prize £10, for Medical and Surgical Anatomy, Midwifery and Therapeutics. The Beaney Scholarship of 30 guineas for Materia Medica (tenable for three years).—For fourth-year students: First prize £25, second prize £10, for Medicine, Surgery, Midwifery and Medical Jurisprudence. The Golding Bird Prize of £33.—For senior students: The Treasurer's Gold Medal for Clinical Medicine; the Treasurer's Gold Medal for Clinical Surgery; the Prize of £25 for Clinical Reports and Commentaries; and the Beaney Prize of 30 guineas for Pathology. The Physical Society awards a prize of £5 to the author of the best Essay on a selected subject; a prize of £7 for the best paper read before the Society, and two prizes of £4 to the members who have most distinguished themselves in the debates of the session. The Gull Studentship in Pathology, of the value of £150 per annum, and the Beaney Studentship in Materia Medica and Therapeutics, of the value of 30 guineas per annum, each tenable for three years, are awarded without competitive examination to enable their holders to carry on research.

Fees.—1. A ticket, including admission to lectures, demonstrations and hospital practice, competition for prizes and eligibility for hospital appointments, may be obtained—(*a*) by the payment of 150 guineas on entrance; (*b*) by the payment of four annual instalments at the commencement of each academical year: first year 40 guineas, second year 40 guineas, third year 40 guineas, fourth year 40 guineas. 2. A reduction is made in the fees for a perpetual ticket in the case of students who have spent one or more years at another medical school. Students entering as third-year students are charged for their first year at Guy's Hospital 35 guineas second and third years 25 guineas each, or 80 guineas in one sum on entrance. This fee is payable by Cambridge students who have passed in Anatomy and Physiology at the Second M B. Examination.

The College.—The College stands upon a site fronting the east gate of the hospital, and is connected with it by a subway. The building serves as a Residential College for Students, and at the same time provides accommodation for the Students' Club. The Clubs' Union ground is less than twenty-five minutes' journey from the Hospital.

KING'S COLLEGE.—The physicians' assistants, the physician-accoucheur's assistant, the ophthalmic clinical assistant, the house surgeons and senior dressers are selected by examination, whilst the ordinary clerkships and dresserships are appointed, in consideration of their former work in the medical school, from amongst the matriculated students. Rooms and commons are provided at the hospital for the resident officers free of charge. Rooms are provided within the walls of the College for the residence of matriculated students.

Scholarships.—Warneford Scholarships: Two of £25 per annum for three years for Literature. One additional Scholarship of £25 per annum for two years will be awarded this year. Science: One of £30 and one of £20, each for two years. Sambrooke: One of £60 and one of £40 for Science. Rabbeth Scholarship of £20 per annum for Science. College Scholarships: One of £40 per annum for two years; one of £30 for one year; three of £20 for one year. The Daniell Scholarship for Chemistry, of the annual value of £20. Sambrooke Registrarships, of the annual value of £50 each and tenable for two years, are open to all matriculated students who have filled any one of the higher appointments of the hospital or who have become Associates. The Leathes Prizes, value £7, and the Warneford Prizes, value £40 are given annually amongst the matriculated medical students. The Todd Medical Clinical Prize consists of a bronze medal and books to the value of £4 4s. The Tanner Prize for Obstetric Medicine, value £10, and the Carter Gold Medal and Prize for Botany, value £15, are given annually in July. Class Prizes, value £3 3s. each, are awarded annually in every subject. A Warneford Scholarship of £35 per annum for two years, for third-year subjects, is awarded annually to resident students only.

LONDON HOSPITAL AND COLLEGE.—The hospital, which is the largest in Great Britain, contains nearly 800 beds. Last year the number of in-patients was 9703, out-patients 128 310, and the number of accidents 12,733.

The following Scholarships and Prizes will be offered for competition during the ensuing winter and summer sessions:—Six Entrance Scholarships of the value of £120, £60, £60 £35, £30 and £20 respectively will be offered for competition in September. The successful candidates must forthwith become full pupils of the hospital and school, if not already entered. An Epsom Scholarship, value £126, for students of Epsom College only. After entrance: Anatomy and Biology Scholarship, £20; Anatomy and Physiology Scholarship, £25; Letheby Prize, Senior, £20; Letheby Prize, Junior, £10; Scholarship in Clinical Medicine, £20; Scholarship in Clinical Surgery, £20; Scholarship in Clinical Obstetrics, £20; Duckworth Nelson Prize, £10; Hutchinson Prize, £35; Sutton Prize, £20; Sir Andrew Clark Prize, £13 10s.; Out-Patient Dressers' Prizes, £60; Practical Anatomy Prizes, £10.

Special classes are held throughout the year for the Preliminary Scientific Intermediate M.B. Examinations of the University of London and for the Primary and Pass Examinations for the Fellowship of the Royal College of Surgeons. Special entries can also be made for Medical and Surgical Practice, the Operative Surgery classes, &c.

Instruction is given throughout the year in all the details required for the diploma in Public Health.

In addition to the regular courses of lectures there will be given during the summer session a course of lectures on Clinical Surgery by Mr. Jonathan Hutchinson, F.R.S., Emeritus Professor of Clinical Surgery.

ST. MARY'S HOSPITAL.—There are three house physicians and three house surgeons, each appointed for six months, and two obstetric officers, each appointed for six months. They board free of expense in the hospital, except that the obstetric officer resides outside the hospital for the first three months. These appointments are awarded after competition, without additional fee. Two demonstrators

of anatomy are appointed annually, with a salary of £70 each; and a demonstrator of physiology, at £100 a year. All these officers are eligible for re-election. Two prosectors of anatomy, assistant demonstrators of anatomy, physiology, chemistry, biology and pathology are appointed annually, and receive an honorarium of £5 each. All students are required to perform the duties of clinical clerk and dresser during the last two years of their curriculum. Students of the third year and of subsequent years are also appointed as clerks and dressers to assist the physicians and surgeons in charge of the out-patients. The hospital contains 281 beds. Two wards are appropriated to the Diseases of Children, and one to those of Women; beds are also provided for Ophthalmic, Aural, and Cutaneous cases. There is an out-patient department for Diseases of Children. Special assistance is given to intending candidates for the final examinations of the Medical, Surgical, and Obstetric tutors. The new wing will present features of the greatest interest in the bearing it must necessarily have upon the future efficiency of the Medical School. The Lying-in Wards will be more especially noteworthy as the first established within a metropolitan general hospital. They will of course be shut off from any direct communication with the other portions of St. Mary's Hospital. This wing will contain (1) a new Out-patients' Department, (2) Lying-in Wards, (3) a Residential College for Medical Officers and Students, (4) additional special Wards, (5) a nurses' Home. This will add 100 beds to the Hospital, making 381 in all, at an estimated cost of £100 000. The prospectus may be had on application to Mr. F. H. Madden, the School Secretary, to Mr. G. P. Field, the Dean, or Dr. A. E. Luff, the Sub-Dean.

Scholarships, Prizes, and Appointments: Scholarships offered for open competition previously to entering at the Medical School.—Entrance Scholarships: The following will be offered for competition on Sept. 24th and 25th at 10 A.M.:—One Scholarship in Natural Science, of the value of 100 guineas, open to any gentleman who has not completed a winter session of study at a medical school. Three Scholarships in Natural Science, each of the value of 50 guineas, under the same condition. One Scholarship, of the value of £133 open to students from Epsom College, being sons of medical men, and who have not completed a winter session of study at a medical school. This Scholarship is not given by competition. Two Scholarships, each of 50 guineas, open to students from the Universities of Oxford, Cambridge, or other University, who have not entered at any London medical school. The examination for the Scholarships will be conducted according to the syllabus of the Preliminary Scientific Examination of London University.

In addition to the Open Entrance Scholarships, Class Prizes, and usual Appointments, Scholarships will be offered for competition at the end of each year, open to all pupils. These Scholarships are of the value of £20, £20, £20 and £20 for the first, second, third, and fourth years respectively.

A residence for students, 33 and 35, Westbourne-terrace, W., in connexion with the hospital, is under the charge of a warden, Mr. E. Roughton, M.D., F.R.C.S., who is prepared to receive applications from students desiring to enter upon residence during the ensuing session. Terms: £75 for the academical year.

Qualified medical men are admitted to unlimited attendance on hospital practice at a fee of £15 15s.

ST. PETER'S HOSPITAL.—The hospital contains 320 beds, and during the past year 3182 patients were treated in the wards and 38,122 attended as out-patients. There is a special department for patients suffering from cancer, consisting of four wards, containing thirty-four beds; here cancer patients are received and attended for a period limited only by the duration of their disease.

Scholarships, &c.—Two Entrance Scholarships, of the value of £100 and £60, are offered for competition just before the commencement of each winter session. One Entrance Scholarship, of the value of £60, open to Oxford and Cambridge students, will be competed for early in October (subjects, Anatomy and Physiology, including Histology). Two Broderip Scholarships, of the value of £60 and £40, are awarded annually to those students in their fourth year who pass the best examination in Clinical Medicine, Clinical Surgery, and Morbid Anatomy. The Murray Gold Medal and Scholarship, founded in connexion with the University of Aberdeen, are awarded every third year to a student of this hospital; it will be next open for competition in May, 1898. The Governors' Prize for Clinical Work and the Lyell Medal for Surgical Anatomy and Practical Surgery are annually open to competition among students at the close of their third year. The Hetley Clinical Prize, value £25, is competed for in the fifth year. Exhibitions, value £5 5s. and £10 10s., are offered for competition at the end of the first and second winter sessions respectively. Class Prizes are also given.

Hospital Appointments.—Clinical Clerkships and Dresserships in all departments are allotted to students without any extra fee. Eighteen Resident Appointments are annually filled from the pupils of the hospital, each appointment extending over six months.

The Curriculum is designed to meet the requirements of the Royal Colleges of Physicians and Surgeons and of the Universities of London, Cambridge, &c. Special Classes are held to prepare students for the Preliminary Scientific M.B. (Lond.) Examination and for the Primary Examination for the diploma of F.R.C.S. Eng.

A Residential College to accommodate about thirty students adjoins the hospital. The charge for residence is £10 10s. and £8 8s. per term, according to the position of the room. Breakfast, luncheon, and dinner are supplied in the College Hall at a very moderate charge.

Fees.—The Composition Fee for the entire curriculum is 120 guineas, or 130 guineas if paid in three instalments. The fee for the Dental Curriculum is 54 guineas, or 60 guineas if paid in two instalments. Students from the Universities and students who have passed the London Preliminary Scientific M.B. Examination are received on special terms.

ST. THOMAS'S HOSPITAL.—*Prizes for the Year 1895–96.*—For First-year students: Two Entrance Scholarships in Natural Science of the value of £150 and £60 respectively, open to all first-year students, will be awarded during the first week in October, after an examination in Physics, Chemistry, and either Physiology, Botany, or Zoology, at the option of the candidate; the William Tite Scholarship, the proceeds of £1000 Consols, is awarded each year; also prizes of £20 and £10; summer, £15 and £10. For Second-year students: The Peacock Scholarship of £38 10s., or the Musgrove Scholarship of £38 10s., are awarded biennially to the students who shall take the highest place in the first-class list in the examinations at the end of the second winter session; they are tenable for two years, provided the holder obtains a place in the first-class in the subsequent winter examination; making the winter prizes £38 10s., £20, and £10; summer, £15 and £10. For Third-year students (winter): Second tenure of Scholarship £38 10s. and prizes of £20, £15, and £10; summer, £15 and £10. The Grainger Testimonial Prize of £15 annually is awarded to students for original work in Anatomy and Physiology. The Cheselden Medal for Surgery and Surgical Anatomy, and the Mead Medal for Practical Medicine, are awarded annually to fourth-year students. The Bristowe Medal annually for Pathology and Morbid Anatomy. The Beaney Scholarship for Surgery and Surgical Pathology, of the value of £52 10s., awarded biennially to students who have completed their fifth but not their seventh year. The Solly Medal, with a prize of from 10 to 20 guineas, will be awarded biennially to a student of the third, fourth, fifth, or sixth year, for the best report of surgical cases. The Treasurer's Gold Medal, for general proficiency and good conduct, is awarded annually to a fourth-year student. There are numerous appointments for students who have completed their courses.

An Entrance Scholarship, of the value of £50, is open to University students. Subjects: Anatomy, Physiology, and Chemistry.

The Salters' Company Fellowship, of the annual value of £100 and tenable for three years, has been established and endowed by the Salters' Company with the view to the promotion of research in Pharmacology.

Fees.—The composition fee to Hospital Practice and Lectures may be paid in the following ways:—1. £180 on entrance in one sum. 2. £157 10s. in instalments: (*a*) by two payments, £85 on entrance and £72 10s. at the beginning of the second year; (*b*) by three payments, £75 at the beginning of the first year, £50 at the beginning of the second year, and £32 10s. at the beginning of the third year; and (*c*) by four payments, £65 at the beginning of the

Digitized by Google

first year, £50 at the beginning of the second year, £30 at the beginning of the third year, and £12 10s. at the beginning of the fourth year. Gentlemen entering at St. Thomas's for Lectures and Hospital Practice of the second and subsequent years pay £130 on entrance, or three instalments of £52 10s., £42, and £42. Students entering for Lectures and Hospital Practice of third and subsequent years pay a composition fee of £80, or £52 10s. on entrance and £31 10s. one year subsequently. The fee for attendance on the general subjects required of students in Dental Surgery is for the two years £65, or, by instalments, £55 for the first year and £15 for the second year. If certificates for Dental Practice are also required the special fee for that subject has to be paid. Qualified practitioners are admitted on payment of a fee of 15 guineas.

UNIVERSITY COLLEGE, LONDON. — *Composition fees.* — 1. For the entire medical education required by the Examining Board in England and the Society of Apothecaries, 135 guineas, if paid in one sum at the commencement of the course; 140 guineas if paid by instalments, as follows—first year, 65 guineas; second year, 50 guineas; third year, 25 guineas. 2. For those students who do not require to attend Chemistry, Pharmacy, and Elementary Biology at a medical school (under the regulations of the Examining Board in England) the fee will be—117 guineas, if paid in one sum; 122 guineas, if paid by instalments, as follows—first year, 55 guineas; second year, 40 guineas; third year, 27 guineas. 3. For the whole course of instruction for the Intermediate Examination in Medicine of the University of London, 55 guineas (paid in one sum). 4. For the course of instruction for the Final M.B. Examination of the University of London, 76 guineas, if paid in one sum; 78 guineas, if paid by instalments, as follows—first year, 45 guineas; second year, 33 guineas. 5. Composition fee for Dental Students, 65 guineas. 6. Composition fee for the whole course of instruction for the Preliminary Scientific (M.B.) Examination of the University of London, 35 guineas.

Exhibitions, Prizes, &c.—Three Entrance Scholarships, one of 131 guineas and two of 55 guineas, are annually awarded, upon examination by printed papers, to gentlemen who are about to commence their first winter attendance in a medical school. The subjects of the examination are Chemistry, Physics, Botany, and Zoology. The Atkinson Morley Surgical Scholarship of £45, tenable for three years, is annually awarded to the student who, upon examination, is found to possess the greatest proficiency in the Theory and Practice of Surgery. The Sharpey Physiological Scholarship of about £120 per annum. Filliter Exhibition, value £30, is awarded annually, in July, to the most proficient student in the class of Pathological Anatomy. An Atchison Scholarship, value about £60 per annum, tenable for two years, is awarded annually. The Cluff Memorial Prize, value about £15, every second year to the most proficient in Anatomy, Physiology, and Chemistry. The Erichsen Prize: a surgeon's operating case of the value of £10 10s., awarded yearly to the student of the class of Practical Surgery who shall most distinguish himself by manipulative skill. The Morris Bursary of £16 a year, tenable for two years. Besides the above, gold and silver medals and other prizes are awarded in each class. Eight house physicians, six house surgeons, four senior and eight junior obstetric assistants are selected annually by examination from among the senior students. The house physicians and house surgeons reside in the hospital for a period of six months, and the senior obstetric assistants for three months, receiving free board and lodging.

Several professors and other gentlemen connected with the College receive students to reside with them; and in the office of the College there is kept a register of persons unconnected with the College who receive boarders into their families; among these are several medical gentlemen and clergymen.

The annual dinner of the old and present students of the Faculty of Medicine will be held at the Hôtel Métropole on Tuesday, Oct. 1st, at 6.30 P.M. Professor Michael Foster, M.D., LL.D., F.R.S., will preside.

WESTMINSTER HOSPITAL.—The hospital contains upwards of 200 beds. There are separate departments for Diseases of the Eye, Ear, Skin, Teeth, and Throat, for Orthopædics, and for Diseases of Women, and a special ward for Children. The Anatomical Museum is open to the students. There are also Pathological and Materia M Museums.

A curator of the museum and a pathologist, with s of £40 and £50 respectively, and a medical and s registrar, each with a salary of £40, are appointed an Two house physicians, two house surgeons, and a re obstetric assistant are appointed for six months after nation, and are provided with rooms and commons two assistant house surgeons with commons only. C assistants to the physicians and surgeons, and to the o in charge of special departments, are appointed from a qualified students of the hospital.

Scholarships and Prizes.—A Natural Science Schola value £60, and the Governors' Scholarship, value £4 offered annually in May; the Guthrie and Entrance Sc ships, value £60 and £40, in October; and a Senior Sc ship, value £40, to Oxford and Cambridge students. A Entrance Scholarship is offered annually to Dental stud A free presentation to pupils of the Epsom Medical Co The Treasurer's Prize, an Exhibition in Anat Physiology, and Chemistry, value £10 10s., tenabl one year, for first-year men. The President's S Scholarship (Anatomy, Histology, and Physiol value £21, given by his Grace the Duke of W minster, President of the Hospital, to a student of second year. At the end of the fourth winter session p of £5 each (books or instruments) in Clinical Medicine Clinical Surgery. Frederick Bird Medal and Prize, v £15. Subjects of examination: Medicine, Midwi Diseases of Women and Children, and Pathology. Chad Prize, £21 (subjects Medicine and Surgery), and the Prize, value £20 (subject Pathology), to students of any not exceeding the fifth. In most of the classes spe prizes. 2 guineas each, are given.

Preliminary Scientific.—Special classes are held in subjects of this examination—Chemistry, Dr. Hake; Phys Mr. Somerville; Biology, Dr. Tims. The extra fee t general student is 12 guineas.

Intermediate M.B.—Advanced Physiology and Histolo Mr. Spencer; Advanced Anatomy, Mr. Black; Orga Chemistry, Dr. Hake; Materia Medica, Dr. Murrell.

D.P.H.—The course of Laboratory Instruction may n be taken. Physics, Mr. Somerville; Chemistry, Dr. Hal Bacteriology, Dr. Blaxall. Fee 12 guineas.

Bacteriology.—A course in General Bacteriology is giv by Dr. Blaxall. Fee £5 5s.

LONDON SCHOOL OF MEDICINE FOR WOMEN, 30, Hand street, Brunswick-square, W.C.—The winter session of th School, which is in connexion with the Royal Free H pital, Gray's-inn-road, will begin on Oct. 1st, 189 and will end on March 30th, 1896. The summ session will begin on May 1st, and will end on Ju 31st, 1896. No students will be admitted to the study Medicine who has not completed her eighteenth year. Th admission of students rests exclusively with the Executi Council.

Scholarships and Prizes.—The Executive Council offe annually a Scholarship of £30 to women preparing for th medical profession. The following scholarships will b offered for competition on Sept. 20th and 21st, 1895:—1. Th School Scholarship, value £30, open to all candidates wh have passed a preliminary examination in Arts recognise by the General Medical Council. 2. The Fanny Butle Scholarship, value £15 a year for four years, open onl to candidates willing to practise in connexion with the Church of England Zenana Missionary Society The Gilchrist Trustees offer occasionally a Scholarship o £50 a year for five years to the student of the School who takes the highest position in the Preliminary Scientific M.B. Examination of the University of London. The John Byron Bursary of £20 a year is open to students requiring aid for the prosecution of their studies; the next award will probably be made in 1896. Two Mackay Prizes of £20 each are given to the students who take the highest number of marks in the Class Examinations for the first two years' work, one being in preparation for the Scotch or Irish Colleges or for the Society of Apothecaries' Examination, and one for the Universities. The Helen Prideaux Memorial Fund gives a prize of £50 every second year to a graduate of the School, for the further prosecution of her medical studies, at the discretion of the trustees. Three Evans Prizes of £3 3s. each are given in the Midwifery Class to enable students to

Digitized by Google

take operative midwifery. There is also a small fund from which assistance can occasionally be given to students and to graduates who specially require pecuniary help to obtain additional experience in operative midwifery. The Wood Prize for Operative Midwifery, value £5 5s., will be offered at the end of the winter session, 1895. Prizes and Certificates of Honour are awarded in each class at the end of the session. Secretary, Miss Heaton.

METROPOLITAN ANCILLARY SCHOOLS OF MEDICINE.

THE following institutions offer a partial curriculum in the form of classes dealing with particular subjects or adapted to special circumstances.

BETHLEM HOSPITAL.—This hospital is open for the admission of two Resident Clinical Assistants who have recently obtained their diplomas to practise Medicine and Surgery. They will be permitted to reside in the hospital for a term generally not exceeding six months, and will be provided with such apartments, rations, and attendance as the Committee shall consider reasonable. They will be under the direction of the Resident Physician, and will be elected by the Committee from candidates whose testimonials appear to be most satisfactory. The students of certain specified London Medical Schools receive Clinical Instruction in the wards of the hospital, and qualified practitioners may attend for a period of three months on payment of a fee. Lectures are also given in connexion with the London Post-graduate Course.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton.—Four House Physicians reside in the hospital for a period of six months. Pupils are admitted to the practice of the hospital: terms, £1 1s. for one month; six months, £5 5s.; perpetual, £10 10s. Lectures and Clinical Demonstrations are given throughout the year by members of the medical staff on Wednesdays and Fridays at four. The medical practice of the hospital is recognised by the University of London, the Apothecaries' Society, and the Army and Navy and Indian Medical Boards. The hospital contains 321 beds in the two buildings.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, Victoria-park.—During the past year 937 in patients have been admitted, and the large number of 28 674 cases have been treated since the opening of the wards in 1855. The number of out-patients treated during 1894 was 17 215 and 536 976 since the commencement of the institution in 1848. Information as to medical instruction can be obtained on application to the Secretary of the Clinical Subcommittee at the hospital. Consulting Physicians: Drs. J. Andrew and E. L. Birkett. Consulting Surgeon: Sir J Eric Erichsen, Bart., F R S. Physicians: Drs. J. C. Thorowgood, Eustace Smith, G. A. Heron, Vincent D. Harris. E. Clifford Beale, and Harrington Sainsbury. Surgeon: Mr. J. F. C. H. Macready, F R C.S. Assistant Physicians: Dr. T. Glover Lyon, Sir Hugh R. Beevor, Bart., and Drs. W. J. Hadley, E. H. Colbeck, Arnold Chaplin, and H. J. Campbell.

CENTRAL LONDON THROAT AND EAR HOSPITAL, Gray's-inn-road.—The hospital contains accommodation for seventeen in-patients, and has a very extensive out-patient department, which is open to all medical practitioners and students for the purpose of clinical demonstration and instruction during the hours of the surgeons' visits. During the past year 7163 out-patients and 257 in-patients were treated. Fee for three months' attendance, 3 guineas; for six months, 5 guineas. A course of lectures on the special diseases treated at this hospital will be delivered during the winter months by members of the staff. The date of these lectures is announced in the medical journals prior to their commencement. They are free to qualified practitioners and advanced students of medicine. Consulting Surgeon: Mr. Thomas Nunn. Surgeons: Mr. Lennox Browne, Dr. Arthur Orwin, Dr. Dundas Grant, Mr. Percy Jakins, and Mr. T. W. Carmalt Jones. Assistant Surgeons: Mr. Wyatt Wingrave and Dr. Holloway. Registrars: Dr. Aberorombie, Dr. Spicer, and Dr. Pegler. Dental Surgeon: Mr. George Wallis. Defects of Speech: Mr. William Van Praagh. Secretary: Mr. Richard Kershaw.

HOSPITAL FOR WOMEN, Soho-square, W.—In connexion with this institution there has been for some years a well-organised Clinical Department. This has been enlarged under the title of the London School of Gynæcology. To meet the want increasingly felt by medical men of an accurate knowledge of the ordinary diseases of women, gentlemen are appointed every three months to act as clinical assistants to the physicians and surgeons seeing out- and in-door patients. The appointments are nominally "open to qualified medical men and to students of medicine after their fourth year," but in the selection of candidates preference is naturally given to gentlemen already engaged in practice. The large numbers of out-patients afford quite unrivalled opportunities for practical instruction in the use of gynæcological instruments and for the study of diseases peculiar to women. A course of lectures on the Anatomy and Physiology of the Female Pelvic Organs is given during each quarter by a member of the Staff. Clinical Lectures are given in the Operating Theatre on alternate Thursdays throughout the winter and summer sessions. Valuable prizes are given, after examination, annually, open to past and present clinical assistants. Fee for the three months' course, £8 8s. Any further information can be obtained by letter addressed to the Dean at the hospital.

COOKE'S SCHOOL OF ANATOMY.—The school is prepared to admit to its supplementary work all who may wish to join the same, but in regard to its curriculum work it does not receive more than half a dozen students in the course of the year. These curriculum students are taken on at reduced fees on the understanding that they shall help in the work of the school from the time of their being capable of doing so till they have passed their examination in Anatomy and Physiology. They are supplied with the necessary material for dissecting the human body two or three times over. The Bland Sutton Presentation, named after Mr. Bland Sutton, F.R.C.S., Sir Erasmus Wilson Lecturer at the Royal College of Surgeons, Surgeon to the Middlesex Hospital, &c. (a former pupil of the school), confers the privilege of free education at the school during the first two years of medical studies. Particulars will be forwarded on application.

The school remains open for anatomical work, not only during the winter, but also during the summer months. Gentlemen rejected at their Anatomical and Physiological Examinations (Second Conjoint, &c.) can get "signed up" from this school for the three or six months' supplementary work they are now required to put in before re-examination. This school is also intended to meet the requirements of qualified practitioners wishing to obtain some of the higher qualifications, and is recognised for the special dissections for the Fellowship of the Royal College of Surgeons. The school possesses a good collection of physiological apparatus. The operations of Surgery are performed by the students on the dead body. Private address: 40 Brunswick square, W.C.

ROYAL HOSPITAL FOR DISEASES OF THE CHEST, City-road. (Established 1814.)—This hospital has been enlarged by the addition of a very complete out-patients' department, and also by the erection of a new wing, which provides accommodation for 80 in-patients. Expenditure for 1894 £8249; income (including legacies), £6692. The attendance of out-patients averages 24 000 annually.

ROYAL EAR HOSPITAL, Frith-street, Soho-square, W. (Founded 1816, for the special treatment of Diseases of the Ear.)—During 1894, 204 in-patients and 2146 out-patients were treated; attendances, 9223 The clinique of the hospital is open to medical practitioners and advanced students by previous arrangement with the Secretary. Surgeons: Mr. Urban Pritchard, Mr. Farquhar Matheson, Mr. Cresswell Baker, and Mr. A. H. Cheatle. Hon. Secretary: Mr. Donald Murray. Secretary: M C. Puddy.

GREAT NORTHERN CENTRAL HOSPITAL, Holloway-road, N. Consulting Physician: Dr. Cholmeley. Consulting Surgeon: Mr. W. Adams. Physicians: Drs. R. Burnet, E. C. Beale, C. E. Beevor H. W. Syers, James Galloway, and A. Morison. Obstetric Physician: Dr. L. Remfry. Surgeons: Messrs. J. Macready, C. B. Lockwood, H. Allingham, P. T. B. Beale, and G. B. M. White. Ophthalmic Surgeon: A. S. Morton. Throat Aural Surgeon: Mr. W. R. H. Stewart. Skin Department: Dr. Cook. Dental Surgeon: Mr. P. Trær Harris. This hospital is now recognised by the Examining Board in England by the Royal College of Physicians and Surgeons as a place of study during the fifth year of the Medical Curriculum. The hospital contains 155 beds, of which 100 are at present occupied. The large rectangular and circular wards, each of which contains 20 beds, the operation theatre, out-patient, general and special, and the pathological departments, have all been erected since 1887. They are specially designed with a view of offering the greatest facilities for clinical work, and contain all the most recent and approved hygienic and antiseptic requirements for

Digitized by Google

the proper care of the sick and for the treatment of disease. Medical practitioners are cordially invited to see the general and special practice of the hospital. In- and out-patient clinical assistants are appointed in the general and special departments and receive certificates at the end of their terms of office. Further particulars from Peyton T. B. Beale, F.R.C.S., Hon. Secretary, Medical Committee, 61, Grosvenor-street, W.

LONDON TEMPERANCE HOSPITAL, Hampstead-road, N.W. (Established 1873.)—Physicians: Sir B. W. Richardson, F.R.C.P., F.R.S., Dr. J. J. Ridge, and Dr. J. Fletcher Little. Surgeon: Dr. W. J. Collins, F.R.C.S. Dental Surgeon: Mr. A. Alexander. The hospital contains 110 beds. The in-patients in 1894 were 1044, and the out-patients and casualties numbered 11,120 new cases. The medical and surgical practice of the hospital is open to students and practitioners. Special departments for Ophthalmology and Gynæcology. Operations: Mondays and Thursdays, 3.30. Classes will be held during the winter and summer sessions for students preparing for the final examinations at the Colleges and the Universities. Appointments, vacancies for which are advertised in the medical journals: Registrar and Pathologist; Resident Medical Officer and Assistant Resident Medical Officer. For particulars as to hospital practice and classes apply at the hospital to Dr. W. J. Collins.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Albany Memorial), Queen-square, Bloomsbury.—The new hospital, with the Finchley branch, contains 180 beds and cots. The physicians attend every Monday, Tuesday, Wednesday, and Friday at 2.30 P.M. In- and out-patient practice and electrical-room treatment at that hour. Physicians: Drs. Ramskill, Hughlings Jackson, Buzzard, Bastian, and Gowers. Physicians for Out-patients: Drs. D. Ferrier, Ormerod Beevor, and Tooth. Assistant Physicians: Drs. James Taylor and J. R. Bradford. Surgeons: Messrs. Victor Horsley and C. A. Ballance. Ophthalmic Surgeons: Messrs. R. Brudenell Carter and Marcus Gunn. Aural Surgeon: Mr. A. E. Cumberbatch. Laryngologist: Dr. Felix Semon. Anæsthetist: Dr. Dudley Buxton. Pathologist: W. S. Colman. Registrar: A. J. Whiting. House Physicians: Drs. Stoddart and Harris. Medical practitioners and senior students may attend the practice after signing their names in the office. Post-graduate and other lectures are given periodically in the hospital by members of the staff, and a scheme for the fuller development of the hospital as a teaching institution is now in course of preparation.

QUEEN CHARLOTTE'S LYING-IN HOSPITAL AND MIDWIFERY TRAINING SCHOOL, Marylebone-road, N.W.—Consulting Physician: Dr. Brodie. Consulting Surgeons: Mr. H. Lee and Sir William MacCormac. Physicians to In-patients: Dr. W. C. Grigg and Dr. W. S. A. Griffith. Physicians to Out-patients: Dr. W. Rivers Pollock and Dr. W. J. Gow. This hospital, which has been recently enlarged, receives over 1000 patients annually, besides having a large out-patient department. Medical pupils are received at all times of the year. Pupils have unusual opportunities of seeing obstetric complications and operative midwifery, on account of the very large number of primiparous cases — nearly three-fourths of the total admissions. Clinical instruction is given on the more important cases which present themselves. Certificates of attendance at this hospital are recognised by all Universities, Colleges, and licensing bodies. Pupil midwives and monthly nurses are received and specially trained. Fees: Medical Students, £5 5s. for two weeks; £8 8s. for four weeks; Qualified Medical Practitioners £5 5s. for four weeks. Pupil Midwives, £26 5s. for three months; Pupil Nurses, £15 15s. for twelve weeks. For further particulars application should be made to Mr. Arthur Watts, Secretary, at the hospital.

SEAMEN'S HOSPITAL SOCIETY, Dreadnought Hospital, Greenwich, S.E. (235 beds). Royal Victoria and Albert Dock Hospital, E. (18 beds). Dispensaries: East India Dock-road, E. and Gravesend.—This institution is established for the relief of seamen of all nations. Casualties are received at all hours. Apartments are provided in the house of the Principal Medical Officer for students. Honorary Consulting Physicians: Dr. Robert Barnes and Sir Richard Quain, Bart., F.R.C.P. Visiting Physicians: Dr. John Curnow and Dr. John Anderson, C.I.E. Visiting Physician to the Royal Victoria and Albert Dock Hospital: Dr. Patrick Manson. Honorary Consulting Surgeon: Mr. J. N. Davies-Colley. Visiting Surgeon: Mr. G. Robertson Turner. Principal Medical Officer: Mr. W. Johnson Smith. Ophthalmic Surgeon: Mr. D. S. Gunn. House Physician: Dr. C. W. Windsor. House Surgeon: Mr. E. P. Isaacs. Branch Hospital:—House Surgeons: Dr. James Rust and Mr. W. Duncan Lawrie. Gravesend Dispensary:—Surgeon: Mr. O. R. Richmond. Secretary: Mr. P. Michelli.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, Bloomsbury, W.C., and Cromwell House, Highgate.—The hospital contains about 180 beds. There are ten Clinical Clerkships, and the number will shortly be increased to sixteen, tenable by all students who have taken out a ticket for the hospital. Senior students should note that there is here a thoroughly organised system of clinical instruction both in the medical and surgical wards. Lectures are given at intervals by members of the staff. The hospital offers great facilities for post graduate teaching and for hospital practice. During the winter session Clinical Lectures on the Medical Cases will be given in the wards or in the museum on Tuesdays by Dr. Sturges and Dr. Lees alternately at 2.30 P.M. and 9.30 A.M. commencing Oct. 10th, and by Dr. Barlow on alternate Mondays at 2.30 P.M., commencing on Oct. 11th. Lectures or demonstrations on the Surgical Cases will be given in the wards or in the theatre by Mr. Owen and Mr. Morgan on alternate Wednesdays at 9.30 A.M. commencing on Oct. 4th, and by Mr. Pitts on alternate Thursdays at 9.30 A.M., commencing on Oct. 12th. The out-patients (medical and surgical) are seen every morning from 9 A.M. to 12 noon. Mondays and Thursdays: Dr. Garrod, Dr. Voelcker, and Mr. Hulson. Tuesdays and Fridays: Dr. Lubbock, Dr. Penrose, and Mr. Lane. Wednesdays and Saturdays: Dr. Colman and Mr. Ballance. Ophthalmic Cases: Mr. Donald Gunn, on Tuesdays at 2 P.M. Ear Cases: Mr. Leopold Hudson, on Thursdays at 9 A.M. Fees: For one month, 1 guinea; for three months, 3 guineas; for one year, 5 guineas. Clinical clerks are appointed from amongst senior students without any additional fee.

ROYAL LONDON OPHTHALMIC HOSPITAL, Moorfields.—The hospital, founded in 1804 and considerably enlarged in 1878, now contains 100 beds for patients, which were occupied during last year by 1961 persons. The out-patients are yearly 25,000; attendances, 113,500 in 1894. Operations are performed daily from 10 A.M. to 1 P.M., and three surgeons attend on each day. Students are admitted to the practice. Fee for six months, £3 3s.; perpetual, £5 5s. Classes, demonstrations, and lectures are periodically given, to which perpetual students are admitted free. Students of the hospital are eligible for the office of house surgeons, or may be appointed clinical and junior assistants. The Secretary, Mr. Robert J. Newstead, will furnish further information as may be desired.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL, King William-street, West Strand.—The hospital contains 30 beds; and the patients, who number 11,000 annually, are seen at 1 P.M., and operations performed daily at 2 P.M. The following are the days of attendance of the surgeons: Mr. Cowell, Mr. Juler and Mr. Griffith, Wednesdays and Saturdays; Mr. Hartridge and Mr. Dodd, Mondays and Thursdays; and Mr. Frost and Mr. D. Gunn, Tuesdays and Fridays. The practice of the hospital is open to practitioners and students. Fees for six months, £3 3s.; perpetual, £5 5s. Students of the hospital are eligible for the post of house surgeon and clinical assistant. Special demonstrations and lectures will be given during the session, commencing in October; for details see weekly journals. Clinical Assistants (who must be duly qualified) to the Surgeons are appointed for periods of six months. Secretary: Mr. T. Beattie-Campbell.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN, Leicester-square, W.C.—The out-patient practice is open to the medical profession at the following times: Every day, except Friday, from 2 to 4 P.M., and Thursday mornings from 10.30 to noon. Specially prepared Clinical Demonstrations, also demonstrations on the different diseases presenting themselves in the out-patient department, followed by Lectures, will be given by Dr. Morgan Dockrell on Wednesday and Saturday afternoons from 2 o'clock P.M. Fee for the complete course, two guineas; or the Wednesday or the Saturday course may be taken separately, at a fee of one guinea for each. Entries should be made with the Secretary, Mr. St. Vincent Mercier.

ST. PETER'S HOSPITAL FOR STONE AND URINARY DISEASES, Henrietta-street, Covent-garden. Established

Digitized by Google

1860. New Hospital built, 1882.—Honorary Surgeons: Mr. F. R. Heycock, Mr. F. Swinford Edwards, Mr. E. Hurry Fenwick, and Mr. Reginald Harrison. Pathologist: Mr. E. Hurry Fenwick. The hospital contains 24 beds and 2 private wards. Consultations are held and operations are performed each Wednesday and Friday at 2 P.M. Medical practitioners and students are invited to the clinical instructions which are given in the wards and out-patient department daily, and to the operations in the theatre on Wednesdays and Fridays at 2 P.M. Average beds occupied daily, 18; average out-patients seen daily, 115.

VOLUNTEER MEDICAL STAFF CORPS (LONDON COMPANIES), Calthorpe-street, Gray's-inn-road, W.C. — Hon. Commandant: Surgeon-General Sir William Guyer Hunter, K.C.M.G., Q.H.S. Commandant: Surgeon-Lieutenant-Colonel A. T. Norton. The Volunteer Medical Staff Corps bears the same relation to the Volunteer Army as the Medical Staff Corps bears to the regular Army. The course of training has the great advantage of affording, in addition to a knowledge of ordinary military duties, special ambulance instruction useful in all ranks of life. All who have gone through the ranks of this corps are capable of rendering valuable aid in any accident, and in cases of emergency may be the means of saving lives which would otherwise be lost. In addition to the Company and Battalion drills of an ordinary infantry corps, the special training includes stretcher, waggon, and litter drill; the use of improvised seats and stretchers; the use and application of bandages, splints &c.; lectures by the officers on first aid to the injured, and on the elements of anatomy, physiology, hygiene, and nursing, which are so arranged as not to interfere with the lectures &c. carried on at the various hospitals in London. There is also a Shooting Club in the corps, in which instruction in, and facilities for, the practice of rifle shooting are given. A Gymnastic Class meets once a week at headquarters, under an instructor who teaches boxing and fencing; "the class is under the special direction of the adjutant and officers, who see that the exercises are consistent with the physical development of the men, an advantage possessed by no other Volunteer corps." Lectures are delivered during the winter session. The Adjutant, Surgeon-Captain D. M. O'Callaghan, will give any information respecting the above on application to the headquarters, Calthorpe-street, Gray's-inn-road, W.C.

SCHOOL OF THE PHARMACEUTICAL SOCIETY OF GREAT BRITAIN.—Chemistry and Physics: Professor Dunstan, M.A., F.R.S., F.I.C. Practical Chemistry: Professor Attfield, Ph.D., F.R.S., F.I.C. Botany: Professor Reynolds Green, M.A., Sc.D., F.R.S., F.L.S., Dean of the school. Materia Medica: Professor Greenish, F.I.C., F.L.S. Practical Pharmacy: Mr. Joseph Ince, F.L.S. The session commences on Wednesday, Oct. 2nd, at 10 A.M. Medical students, or pupils intending to enter the medical profession, are admitted to the lectures and laboratory work in any or all the courses. Certificates of instruction in this school are received by the Conjoint Board of the Royal Colleges. Application for admission to the school, or for further information, may be made to the Secretary of the school, 17, Bloomsbury-square, London, W.C. The introductory address will be delivered by Dr. F. T. Roberts, Professor of Medicine, University College Hospital, on Wednesday, Oct. 2nd, at 3 P.M.

CITY SCHOOL OF CHEMISTRY AND PHARMACY, LIMITED, 27, Chancery-lane, W.C.—This school was established in 1882 for the advancement of pharmaceutical education. Lecturers and Demonstrators: Mr. Maurice Williams, Principal; Mr. Thomas A. Ellwood, F.I.C., F.C.S. &c.; Mr. Martin J. Cole, Microscopist; Mr. Herbert J. Killick, Secretary and Curator. Subjects: Theoretical and Practical Chemistry, Chemical Physics, Theoretical and Practical Pharmacy, Materia Medica, and Therapeutics. Lectures and Demonstrations are given daily by the Principal, and the student is allowed unlimited laboratory and pharmacy practice. Application for particulars should be made to the Principal.

SOUTH LONDON SCHOOL OF PHARMACY, LIMITED.—This school was established in 1868 and incorporated in 1888. The managing director is Dr. John Muter, M.A., F.R.S.E., F.C.S., F.I.C., who lectures on Chemistry, Physics, and Botany. The other Lecturers are: Mr. W. H. Dodd, F.C.S. (Materia Medica and Pharmacy); Mr. L. De Koningh, F.I.C., F.C.S. (Analytical Chemistry); assisted by a staff of competent demonstrators. The department most valuable to medical students is the Medical and General Science Tutorial Department. The subjects taught are: For First B.Sc. and Preliminary Scientific: Inorganic and Practical Chemistry. For First M.B.: Organic Chemistry, Analysis and Pharmaceutical Chemistry, and Materia Medica. For Apothecaries' Hall and the Conjoint Colleges: Chemistry, Botany, and Materia Medica. For Pass M.B. Lond: Practical Toxicology and Forensic Medicine. For Sanitary Science qualifications: Practical Chemistry and Microscopy. Particulars as to fees may be had from the Secretary, 325, Kennington-road, London S.E.

WESTMINSTER COLLEGE OF CHEMISTRY AND PHARMACY, Trinity square, Borough, S.E.—The school was established in 1872, and under the directorship of Mr. G. S. V. Wills, F.L.S., F.R.M.S., &c., gives instruction in Chemistry and Physics, Materia Medica and Pharmacy, to Medical and Dental students.

GRIFFITHS'S COLLEGE OF CHEMISTRY AND PHARMACY, 12, Knowle-road, Brixton, S.W.—Instruction is given in Chemistry, Physics, Botany, Biology, Microscopy, Toxicology, &c., for the examinations of the Apothecaries' Hall, Conjoint Board, First M.B. London, Durham, special examinations for B.A. of Cambridge. During the present academic year 34 candidates passed the examinations of the Pharmaceutical Society, 8 passed the Hall, 3 passed the London Preliminary Science, 1 passed Durham, 1 passed the First M.B. London, and 1 passed Royal Navy (Surgeon in). Particulars as to fees may be had from Dr. A. B. Griffiths, F.R.S. Edin., F.C.S., at the above address.

ROYAL COLLEGE OF SCIENCE, London (with which is incorporated the ROYAL SCHOOL OF MINES).—Mechanics and Mathematics: Mr. A. R. Willis, D.Sc. Biology: Mr. G. B. Howes, and Mr. J. B. Farmer, M.A. Chemistry: Professor W. A. Tilden, F.R.S., and Dr. W. P. Wynne. Physics: Professor A. W. Rücker, F.R.S., and Mr. C. V. Boys, F.R.S. Astronomical Physics: Professor J. N. Lockyer, F.R.S. Geology: Professor J. W. Judd, F.R.S. Metallurgy: Professor W. C. Roberts Austen, F.R.S. Mining: Professor C. Le Neve Foster, F.R.S. Agriculture: Professor J. Wrightson. The College reopens on Wednesday, Oct. 2nd, 1895. Communications should be addressed to the Registrar, Royal College of Science, South Kensington, S.W.

ELECTRICAL STANDARDIZING, TESTING, AND TRAINING INSTITUTION, Faraday House, Charing-cross-road, W.C.—Principal, Mr. Hugh Erat Harrison, B.Sc. Lond., F.C.S., A.M.I.C.E., M.I.E.E. Instructor in Mathematics: Alexander Russell, M.A. Glasgow and Cambridge. Instructor in Chemistry: Chas. J. Wilson, F.I.C., F.C.S. This institution, in addition to its ordinary course of training in electrical engineering, which occupies two or three years, also arranges for special instruction in all branches of electricity, either by private tuition or by a specially arranged course at the college or at the works of the companies with which it is associated. There are Entrance Scholarships of the value of 80 and 50 guineas, and Exhibitions of 40 guineas. Particulars may be obtained on application to the Secretary, Mr. Howard Foulds, Faraday House, Charing-cross-road, W.C.

HOSPITALS AFFORDING FACILITIES FOR CLINICAL OBSERVATION.

EAST LONDON HOSPITAL FOR CHILDREN AND DISPENSARY FOR WOMEN, Glamis-road, Shadwell, E.—Physicians: Dr. Eustace Smith, Dr. Horatio B. Donkin, Dr. J. A. Coutts, and Dr. Dawson Williams. Surgeons: Mr. R. W. Parker and Mr. L. A. Dunn. Assistant Physicians: Dr. H. J. Campbell, Dr. T. H. Arnold Chaplin, Dr. J. A. Hayward, and Dr. Morley Fletcher. Assistant Surgeon: Mr. H. B. Robinson. Administrator of Anæsthetics: Mr. Thomas Bird. Resident Medical Officer: Mr. Percy C. Phillips. House Surgeon: Mr. A. W. G. Bagshawe. House Physician: Dr. R. P. Cockburn. Secretary: Mr. Thomas Hayes. The hospital maintains 102 cots, and on an average 178 out-patients are seen daily. Clinical instruction is given by the physicians and surgeons to the hospital, as announced in the advertisement columns. All particulars may be obtained on application to the Secretary.

EVELINA HOSPITAL FOR SICK CHILDREN, Southwark-bridge-road, S.E.—Consulting Physicians: Dr. W. S. Playfair, Dr. J. F. Goodhart, and Dr. Frederick Taylor. Physicians: Drs. Nestor Tirard and Frederick Willcocks. Physicians to Out-patients: Drs. George Carpenter and W. Soltau Fenwick. Ophthalmic Surgeon: Dr. W. A.

Digitized by Google

Bralley. Consulting Surgeons: Messrs. W. Morrant Baker, H. G. Howse, and R. Clement Lucas. Surgeons: Messrs. G. H. Makins and F. S. Eve. Surgeons to Out-patients: Messrs. J. H. Targett and A. H. Tubby. Dental Surgeon: Mr. R. Denison Pedley. Senior Resident Medical Officer: Mr. Arthur Quennell. Junior Resident Medical Officer: Dr. Edwin Sly.

VICTORIA HOSPITAL FOR CHILDREN, Chelsea, S.W. (with which is incorporated ST. GABRIEL'S HOSPITAL FOR INFANTS).—The hospital contains 90 beds and has a large out-patient department (nearly 1000 weekly); the home at Broadstairs has 50 beds. Consulting Surgeons: Sir John Erichsen and Mr. Cowell. Physicians: Dr. Ridge Jones and Dr. Dawtrey Drewitt. Physicians to the Out-patients: Drs. Montague Murray, Walter Carr, W. Wallis Ord, and Humphry D. Rolleston. Surgeons: Messrs. Pick and D'Arcy Power. Surgeons to the Out-patients: Messrs. Raymond Johnson and H. F. Waterhouse. Ophthalmic Surgeon: Mr. W. J. Holmes Spicer. Dental Surgeon: Mr. Percy Smith. Anæsthetist: Dr. Paul Frank Moline. House Surgeon: Mr. A. Chaning Pearce, M.R.C.S., M.B. Lond. House Physician: Mr. Toft Barker, M.R.C.S. Secretary: Captain W. C. Blount, R.N. Out-patients are seen as under:—Medical and Surgical Cases: Daily, at 12.30 P.M., and every afternoon at 1.30 P.M. Dental Cases: Saturdays, at 9 A.M.

WEST LONDON HOSPITAL, Hammersmith-road, W.—This hospital has 101 beds, but the erection of a new wing which will contain another 72 beds is now nearly completed. About 1700 in-patients and 20,000 out-patients, whose attendances number 60,000, are treated annually. There are appointments for two House Physicians and two House Surgeons, with board and residence, tenable for six months; also appointments for a limited number of Clinical Assistants. Physicians: Drs. D. W. C. Hood, F. G. D. Drewitt, and J. B. Ball. Physician for Diseases of Women: Dr. Albert J. Venn. Surgeons: Messrs. C. B. Keetley, F. Swinford Edwards, and S. Paget. Surgeon for Diseases of the Eye: Mr. B. J. Vernon. Assistant Physicians: Drs. Seymour Taylor, A. E. Garrod, W. Hunter, and W. A. Turner. Assistant Physician for Diseases of Women: Dr. J. A. Mansell Moullin. Assistant Surgeons: Messrs. L. A. Bidwell, G. L. Cheatle, and W. McA. Eccles. Assistant Surgeon for Diseases of the Eye: Mr. H. P. Dunn. Surgeon-Dentist: Mr. H. Lloyd Williams. Physician-in-Charge of Throat and Nose Department: Dr. J. B. Ball. Surgeon-in-Charge of Aural Department: Mr. S. Paget. Surgeon-in-Charge of Orthopædic Department: Mr. C. B. Keetley. Pathologist: Dr. W. Hunter. Dermatologist: Mr. P. S. Abraham. Administrators of Anæsthetics: Messrs. T. Gunton Alderton, Rickard W. Lloyd, and E. W. Lewis. Electrician: Dr. F. O. Buckland. Secretary: Mr. R. J. Gilbert. The practice of the Hospital is open to practitioners and to senior students (on payment of a small fee); clinical assistants are appointed to the wards, and clinical instruction is given in the out-patient department. Courses of post-graduate lectures are given by the staff on Wednesdays at intervals, particulars of which are advertised in the medical journals. Further information can be obtained on application to the Honorary Secretary of the medical staff, Mr. L. A. Bidwell, at the hospital.

NORTH-EASTERN HOSPITAL FOR CHILDREN, Hackney-road, Shoreditch, N.E. For the sick children of the poor under twelve years of age. Established 1867. City Offices: 27, Clement's-lane, E.C.—Fifty-eight beds. Last year 701 in-patients and 13,124 out-patients (representing 47,313 attendances) were relieved, 198 of the in-patients being under two years of age. Consulting Physicians: Drs. A. E. Sansom, W. Cayley, and F. C. Turner. Consulting Surgeons: Messrs. Jonathan Hutchinson, Waren Tay, and R. J. Godlee. Physicians: Drs. W. A. Wills, James Taylor, H. G. Adamson, and J. H. Sequeira. Surgeons: Messrs. Bilton Pollard and H. Percy Dean. House Surgeon: Dr. G. M. Edwards. House Physician: Mr. G. J. K. Martyn. Junior House Physician: Mr. Percy E. Adams. Lady Superintendent: Miss E. W. Curno. Secretary: Mr. T. Glenton-Kerr. The surgeons attend on Wednesdays at 2 P.M. and Fridays at 9 A.M.; the physicians daily at 2 P.M. The practice of the hospital is open (free) to students of either sex.

NORTH-WEST LONDON HOSPITAL, Kentish Town-road.—This hospital provides 53 beds and has a large out-patient department. There are appointments for two Resident Medical Officers, with board, residence, and washing. The Senior Medical Officer also receives £50 per annum. Honorary Medical Staff:—Consulting Physician: Dr. Donald W. Hood. Physician: Dr. Harry Campbell. Surgeon: Mr. Frederic Durham. Assistant Physicians: Drs. Walter Sibley, Leonard G. Guthrie, and James Cagney. Assistant Surgeons: Messrs. M. P. Mayo Collier, C. Gordon Brodie, J. Jackson Clarke. Accessory Staff: Drs. J. Herbert Stowell, John Shaw, and Wm. J. Collins, and Mr. C. F. Ribbett. Resident Medical Officer: Mr. H. N. D. Mackenzie. Assistant Medical Officer: Mr. J. S. Hosford. Secretary: Mr. Alfred Craske.

ENGLISH PROVINCIAL HOSPITALS AND MEDICAL SCHOOLS.

MASON COLLEGE, BIRMINGHAM.—Two Ingleby Scholarships are offered annually after examination in Obstetric Medicine and Surgery and Diseases of Women and Children. The Scholarships are open to students who have completed two years of their curriculum in this college. One or more Sydenham Scholarships will be offered annually of the value of 30 guineas each. The orphan sons of former students of the Birmingham Medical School have priority of election. No Sydenham scholars are elected whose age exceeds twenty-three years on the day of election. Scholarships are held for three years, subject to good behaviour. A Queen's Scholarship will be offered annually of the value of 30 guineas. It may be held for three years, one-third being paid each year, subject to good behaviour. A Sands Cox Scholarship is offered annually, of the same value as the last, and is held under similar conditions. The Russell Memorial Prize is awarded annually after examination in Nervous Diseases. There are Faculties of Arts, Science, and Medicine, and students are prepared for the various examinations of the University of London. The medical courses qualify for the diplomas of all Licensing Bodies and for the degrees in Medicine and Surgery of British Universities. There are various Scholarships on Entrance and otherwise. The Dental Department, in conjunction with the General, Queen's, and Dental Hospitals, affords a complete curriculum for all Dental diplomas. The Library contains upwards of 24,000 volumes. Syllabus containing full information as to the various courses of instruction, lecture days and hours, fees, scholarships, etc., will be forwarded on application to the Registrar.

GENERAL AND QUEEN'S HOSPITALS, BIRMINGHAM. *General Hospital*: Consulting Physicians: Dr. Fletcher Sir W. Foster, and Dr. Wade. Consulting Surgeon: Mr. Pemberton. Physicians: Drs. Rickards, Saundby, Stephens, and Wilson. Surgeons: Messrs. Chavasse, Barling, Harrison, and Heaton. Obstetric Officer: Dr. Malins. Assistant Physicians: Drs. Short and Russell. Assistant Surgeons: Messrs. Lucas and Gamgee. Assistant Obstetrical Officer: Dr. Thos. Wilson. Beds, 271; average occupied. Patients in 1894: in-patients, 4336; out-patients, 49,83

UNIVERSITY COLLEGE, BRISTOL (Faculty of Medicine). Students can complete in Bristol the entire course of study required for the Medical and Surgical degrees of the University of London, and for the diplomas of the Royal College of Physicians of London and the Royal College of Surgeons of England, the Apothecaries' Society of London, and the Army and Navy Boards. The lectures and instruction given in the Faculty of Arts and Science are adapted to the various Preliminary Arts Examinations above referred to and also to the Matriculation and Preliminary Scientific examinations of the University of London; whilst the Faculty of Medicine, the Royal Infirmary, and the General Hospital together provide for every detail of the professional curriculum required by the University of London and the various examining boards. All necessary information may be obtained from the Dean of the Faculty of Medicine, Prof. E. Markham Skerritt, M.D., F.R.C.P.

UNIVERSITY COLLEGE, CARDIFF, MEDICAL SCHOOL. Owing to the very rapid increase in the population of Glamorganshire and Monmouthshire, and the consequent increase in the Infirmary accommodation, the basis on which to build a Medical School in South Wales is amply sufficient for every need. University College, Cardiff, has for some years past prepared students in Physics, Chemistry, Zoology and Botany; and these students have in consi-

Digitized by Google

numbers passed these subjects as part of their medical curriculum and have finished their studies elsewhere. The recent appointments of a Professor of Anatomy, a Professor of Physiology, and of a Lecturer on Materia Medica and Pharmacy will afford facilities to students who may wish to continue their studies in Cardiff until the end of their third year. Large laboratories are now ready; they comprise spacious lecture-rooms to seat 100 students each, a dissecting-room, anatomical museum, bone-room, and preparation-room; a class-room for practical physiology, physiological preparation and research rooms, and photographic and instrument-rooms, and museum of Materia Medica. Students preparing for the Preliminary Scientific and Intermediate Examination in Medicine of the University of London or Durham may compound for their classes by paying a composition fee of £57 10*s*. The College classes are recognised by the Scottish Universities. Students who are preparing for the examinations of the Conjoint Board or of the Society of Apothecaries, London, may compound for their classes by paying a composition fee of £47 10*s*. In all cases the composition fees may be paid in instalments, and fees include hospital attendance. Physics.—Professor J. Viriamu Jones, M.A. Oxon., B.Sc. Lond., Fellow of University College, London, F.R.S. Assistant Professor: A. L. Selby, M.A., Fellow of Merton College, Oxford. Demonstrator and Assistant Lecturer: W. S. Hensley, B.A., Christ's College, Cambridge. Chemistry. — Professor C. M. Thompson, M.A., Trinity College, Cambridge, D.Sc. Lond., F.C.S. Assistant Lecturers: E. P. Perman, D.Sc. Lond., and A. A. Read, F.I.C., F.C.S. Biology. — Professor W. N. Parker, Ph.D. Freiburg, F.Z.S. Assistant Lecturer: A. H. Trow, B.Sc. Anatomy. — Professor Alfred W. Hughes, M.B., F.R.C.S. Eng. and Edin. Physiology. — Professor John Berry Haycraft, M.D., D.Sc., F.R.S.E. Materia Medica: D. R. Paterson, M.D. The Infirmary, within three minutes of the College, is provided with 200 beds. Attached to the hospital is a large out-patient department and special departments for the Eye, Ear, and Throat. Further information may be obtained from Dr. John Berry Haycraft, Dean of the Medical Faculty.

BRISTOL ROYAL INFIRMARY (founded 1735).—270 beds. Honorary and Consulting Physicians: Dr. Edward Long Fox and Dr. William H. Spencer. Honorary and Consulting Surgeons: Mr. Augustin Prichard and Mr. Edmund C. Board. Physicians: Dr. R Shingleton Smith, Dr. Henry Waldo, Dr. John E. Shaw, and Dr. Arthur B. Prowse. Obstetric Physician: Dr. W. C. Swayne. Assistant Physicians: Dr. P. Watson Williams and Dr. F. H. Edgeworth. Surgeons: Mr. Arthur W. Prichard, Mr. J. Greig Smith, Mr. W. H Harvant, and Mr. J. Paul Bush. Ophthalmic Surgeon: Mr. F. Richardson Cross. Dental Surgeon: Mr. W. R. Ackland. Assistant Surgeons: Mr. G. Munro Smith and Dr. James Swain. Pathologist: Dr. Theodore Fisher. House Surgeon: Mr. Thomas Carwardine. House Physician: Mr. H. F. Mole. Junior House Surgeon: Mr. R. C. Leonard. Junior House Physician: Mr. M. C. Barber. Secretary and House Governor: Mr. E. A. Leonard.

Scholarships and Prizes.—Two Entrance Scholarships, 35 guineas and 10 guineas, awarded annually in October after examination in general subjects; Surgical and Medical Suple Gold Medals, 5 guineas each, with 7 guineas added in money; Clark Prize, 11 guineas; Crosby Leonard Prize, 7 guineas; Tibbitts Prize, 9 guineas; Midwifery Prize, 3 guineas in books or instruments; Pathological Prize, 6 guineas; Ophthalmic Prize, 3 guineas in books or instruments; Dental Prize, 3 guineas in books or instruments.

There are four resident appointments—viz., House Surgeon, House Physician, Junior House Surgeon, and Junior House Physician, the last two of which are intended specially for qualified students of the Bristol Royal Infirmary, who are elected after a practical examination. Medical Registrars and Surgical Registrars are appointed for periods of six months. The Dressers reside in the Infirmary in rotation, free of expense. The Maternity student also has rooms in the Infirmary. The whole of the clinical work has been carefully rearranged to meet the requirements of the five years' curriculum. There is class instruction in the wards by the physicians and surgeons on five days a week, in addition to the regular clinical lectures. Practical instruction in Dental Surgery at 1 P M on Tuesdays and Fridays. Clinical Clerkships and Dresserships, 5 guineas for each six months. Perpetual Medical and Surgical Practice, 35 guineas in one sum. There are special departments for Diseases of Women, the Eye, Ear, Throat, &c, with Clerkships and Dresserships attached.

Further information can be obtained from Dr. Arthur B. Prowse, Dean of the Faculty.

BRISTOL GENERAL HOSPITAL.—200 beds. Physicians: Drs. Markham Skerritt, Harrison, and Michell Clarke. Physician to Throat and Nose: Dr. Barclay Baron. Assistant Physician: Dr. Parker. Surgeons: Messrs. Pickering, Penny, Barclay, and Morton. Assistant Surgeon: Mr. Lansdown. Registrar: Mr. Fisher. Anæsthetist: Mr. Freeman. House Surgeon: Mr. Firth. Physicians' Assistant: Mr. F. E. Peake. Assistant House Surgeon: Mr. C. M. Phillips. Clinical Clerkship, six months, £5 5*s*. Dresserships, six months, £5 5*s*. Obstetric Clerkship, three months, £3 3*s*. Special clinical instruction is given in Diseases of the Skin, Eye, Ear, and Throat, also in Diseases of Women and in Dental Surgery. Further information may be obtained of the Secretary, at the hospital, or from Dr. Markham Skerritt, Dean of the Hospital Faculty.

Scholarships and Medals. — Lady Haberfield Entrance Scholarship: This Scholarship, founded in 1875, of the value of about £30, being the interest of £1000 bequeathed for the purpose by the late Lady Haberfield, is awarded annually at the commencement of the winter session after a competitive examination in subjects of general education. Second Entrance Scholarship: An additional Entrance Scholarship of the value of £20 is awarded when more than six candidates present themselves. Clarke Scholarship: A Surgical Scholarship, of the value of £15, founded by H. M. Clarke, Esq., of London is awarded annually at the end of the winter session after an examination in Surgery. Sanders Scholarship: A Scholarship founded by the late John Nash Sanders, Esq., of the value of £22 10*s*., is awarded annually at the end of the winter session after examination in Medicine, Surgery, and Diseases of Women. Martyn Memorial Pathological Scholarships, founded in 1878 by public subscription, in memory of the late Dr. Samuel Martyn, Physician to the hospital: Two Scholarships, each of the value of £10, are awarded annually: one at the end of the summer session and one at the end of the winter session. A student may, at the option of the Faculty, hold both these Scholarships. After a competitive examination in Pathology and Morbid Anatomy the successful candidate is appointed Pathological Clerk to the hospital for the term of six months. Committee Gold Medal: This medal, presented by the committee of the hospital, is awarded annually at the end of the winter session to the student of the fourth year who has most distinguished himself during his career at the hospital and medical school. Committee Silver Medal: This medal, presented by the committee of the hospital, is awarded annually at the end of the winter session to the next most distinguished student of the fourth year. The rules relating to the several Scholarships may be had on application.

CAMBRIDGE: ADDENBROOKE'S HOSPITAL.—Clinical Lectures in Medicine and Surgery, in connexion with the Cambridge Medical School, are delivered at this hospital twice a week during the academical year; and practical instruction in Medicine and Surgery in the wards and out-patients' rooms is given by the physicians and surgeons daily, during the vacations as well as term time. Instruction is also given in all the special modes of medical and surgical investigation. Clinical Clerks and Dressers are selected from students according to merit, and without payment. The composition fee for pupilship is 8 guineas.

UNIVERSITY OF DURHAM COLLEGE OF MEDICINE, Newcastle-upon-Tyne.—The following Scholarships and Prizes are awarded annually:—A University of Durham Scholarship, value £100, for proficiency in Arts, awarded to full students in their first year. The Dickinson Scholarship, value interest of £400, and a Gold Medal, for Medicine, Surgery, Midwifery, and Pathology. The Tulloch Scholarship, value the interest of £400, for Anatomy, Physiology, and Chemistry. The Charlton Scholarship, value the interest of £700, for Medicine. The Gibb Scholarship, value the interest of £500, for Pathology. The Goyder Memorial Scholarship (at the Infirmary), value the interest of £325, for Clinical Medicine and Clinical Surgery. The Luke Armstrong Memorial Scholarship, value the interest of £680. The Stephen Scott Scholarship in Surgery, value the interest of

£1000. Heath Scholarship: The late George Yeoman Heath, M.D., M.B., D.C.L., F.R.C.S., President of the University of Durham College of Medicine, has bequeathed the sum of £4000 to found a Scholarship in Surgery, the interest to be awarded every second year; the first award will be in 1896. The Gibson Prize, interest on £225, in the department of Midwifery and Diseases of Women and Children. At the end of each session a Prize of Books and Honours Certificates are awarded in each of the regular classes. Assistant Demonstrators of Anatomy, receiving each an honorarium of £5, Prosectors, and Assistant Demonstrators of Physiology and Pathology are elected yearly. Pathological Assistants, Assistants to the Dental Surgeon, Assistants in the Eye Department, Throat and Ear Department, and Skin Department, Clinical Clerks, and Dressers are appointed every three months.

NEWCASTLE-UPON-TYNE ROYAL INFIRMARY.—Physicians: Drs. Philipson, Drummond, Oliver, and Limont. Surgeons: Drs. Arnison, Hume, and Page, and Mr. Williamson. Assistant Surgeons: Mr. James Rutherford Morison, Mr. W. Glaholm Black, Mr. Walter Ridley, and Mr. A. M. Martin. Pathologist: Dr. Drummond. Dental Surgeon: Mr. R. L. Markham. Skin Department: Dr. Limont. Eye Department: Mr. Williamson. Throat and Ear Department: Mr. Ridley. Senior House Physician: Dr. T. Beattie. Anæsthetist: Dr. W. D. Arnison. Surgical Registrar: Mr. W. G. Richardson. The infirmary contains 280 beds. Clinical Lectures are delivered by the Physicians and Surgeons in rotation. Pathological Demonstrations are given as opportunity offers by the Pathologist. Practical Midwifery can be studied at the Newcastle Lying-in Hospital. Instruction is given in Psychological Medicine at the Coxlodge Lunatic Asylum. A Special Course of Instruction is given in the City Hospital for Infectious Diseases by the Superintendent, the City Officer of Health, Mr. H. E. Armstrong.

LEEDS GENERAL INFIRMARY AND MEDICAL DEPARTMENT OF THE YORKSHIRE COLLEGE.—The Leeds General Infirmary has accommodation for 471 in-patients, medical and surgical, including forty-two beds at a "semi-convalescent home" in the country. During the last year 5714 in-patients and about 40,000 out-patients were treated. Clinical teaching takes place daily in the wards, and Clinical Lectures are given in Medicine and Surgery by the Physicians and Surgeons. There are Medical, Surgical, Ophthalmic, Aural, and Electrical Departments, in each of which special instruction is imparted to students A Gynæcological and Extern Obstetric Department, together with Laryngeal and Skin Clinics, are in operation. The Public Dispensary, the Hospital for Women and Children, the Fever Hospital, and the West Riding Lunatic Asylum are other medical institutions which are made use of by the Leeds students. In October last the new buildings of the Medical School were opened by their Royal Highnesses the Duke and Duchess of York. Erected on a commanding site, close to the Infirmary, the New School of Medicine contains complete accommodation for the training of medical students upon the most approved modern methods. A very fine dissecting-room, extensive laboratories for Physiology and Pathology, with the most recent improvements in fittings and apparatus, ample lecture-room accommodation, a large Library, and separate Museums for Pathology and Anatomy—these are some of the most striking features of the new buildings. Careful provision for the convenience of students, in the shape of a common-room, a refectory, &c., has also been made a feature of the school. The classes in Systematic and Practical Chemistry, Physics and Biology, and Practical Toxicology are held in the Science and Arts Department of the College, in College-road. Two Entrance Scholarships are offered: one, of the value of 64 guineas, covering admission to all requisite lectures; and the other, of the value of 40 guineas, covering the cost of admission to the medical and surgical practice of the infirmary. Several valuable prizes are given at the end of each session. The following appointments at the infirmary are annually open to students: Resident medical officer, resident surgical officer, resident casualty officer, resident ophthalmic officer, appointed for twelve months, and eligible for re-election; resident obstetric officer, 2 house physicians, holding office for twelve months; 4 house surgeons, for twelve months; 36 physicians' clerks, for six months; 32 surgeons' dressers, for six months; 16 ophthalmic and aural surgeons' dressers, for three months; 16 gynæcological ward clerks, for three months; 12 gynæcological out-patient clerks, for three months; 32 assistant physicians' clerks, for three months; 32 assistant surgeons' dressers, for three months; 32 dressers in the casualty-room, for three months; 32 post-mortem clerks, for three months.

There are appointments open to students in other medical institutions in the town and also in the West Riding Lunatic Asylum.

UNIVERSITY COLLEGE, LIVERPOOL.—In addition to the £25,000 presented to the College last year by the Earl of Derby and Mr. George Holt for the endowment of the chairs of Anatomy and Pathology, the Medical School has been further enriched by a donation of £15,000 from the Rev. S. A. Thompson Yates for the erection of new Physiological and Pathological Laboratories. These are now in course of erection, and the laying of the foundation-stone will form part of the ceremony at the opening of the coming session. The Chemical Laboratories are at present being extended, so as to provide *inter alia* more complete accommodation for those engaged in Laboratory work for Diplomas in Sanitary Science. Still more recently steps have been taken towards providing for the extension of the Anatomical Department, and structural alterations for this purpose are at present in progress. During the past year the electric light has been introduced into the dissecting-room and theatre. The chair of Pathology has secured adequate temporary accommodation in Ashton Hall, an institute adjacent to the College, which has been recently opened, and contains ample class-room and laboratory appliances for study and research in Pathology and Bacteriology.

The Museums of Anatomy, Pathology, Materia Medica, and Public Health are furnished with complete provision for the needs of students, and have recently been reorganised and revised.

ROYAL INFIRMARY.—The Royal Infirmary, which adjoins the School, contains 300 beds, with 40 special beds for the treatment of Diseases of Women. The Lock, Lying-in, Eye and Ear, Children's, and Dental Hospitals are in the immediate vicinity, and their practice is open to students of the Medical Faculty.

Fees.—The composition fee for lectures and classes is £24 15*s.* for Preliminary Science Classes: £60 for the Medical Classes required for the Victoria University degrees; £70 for all the classes required for the diplomas of the Conjoint Boards. The medical composition fees are payable in two instalments at intervals of twelve months. The fee for hospital attendance at the Royal Infirmary is 40 guineas, also payable in two annual instalments.

Appointments.—Three house surgeons, three house physicians, and one external house surgeon to the Thornton Wards are appointed for six months after (if necessary) competitive examination. Candidates must have a legal qualification. Three clinical clerks for each physician, three or more dressers for each surgeon, and two clerks to the Thornton Wards for Diseases of Women are appointed every three months. Post-mortem clerks are appointed for six weeks; all students are required to perform this duty before the schedule for the Final Examination is signed.

Scholarships.—(*a*) Two Holt Tutorial Scholarships, each of the value of £100 for one year, are awarded annually by the Medical Faculty to senior students. The successful candidates are required to devote a year to tutorial work and investigation in the Anatomical and Physiological Departments. (*b*) Two Lyon Jones Scholarships of the value of £21 each for two years are awarded annually: a Junior Scholarship, open to Victoria University students at the end of the first year of study, in the subjects of the first M.B. examination; and a Senior Scholarship, open to all students at the end of the third year of study in the subjects of Anatomy, Physiology, and Materia Medica. (*c*) The Derby Exhibition of £15 for one year is awarded in Clinical Medicine and Clinical Surgery in alternate years. Students may compete in their fourth or fifth year. In 1896 the subject will be Clinical Surgery. (*d*) The Torr Gold Medals in Anatomy and Physiology and class prizes are awarded annually.

Communications should be addressed to the Dean, Professor Paterson, M.D., University College, Liverpool.

MEDICAL DEPARTMENT OF OWENS COLLEGE, VICTORIA UNIVERSITY.—This medical school is located in a large new building, which forms a part of Owens College. It is provided with a very large dissecting-room, physiological

Digitized by Google

laboratory, private laboratories, and work-rooms, besides lecture-rooms, a museum, and a library. In order to give the fullest possible opportunities for teaching and investigation in the departments of Anatomy, Physiology, Pathology, and Materia Medica, an extension of the school buildings has been made. The additions were recently opened by the Duke of Devonshire, President of the College, and occupy a parallelogram bounded on three sides by Coupland-street, Lloyd-street, and Walter-street. The greater part of the buildings is devoted to the departments of physiology, pathology, toxicology, anatomy, and public health. The new physiological department occupies more than half of the new buildings, and includes a large lecture theatre, accommodating 350 students, with preparation and diagram rooms adjacent to it, and a research laboratory fitted with the necessary apparatus for the use of advanced students, research scholars, or practitioners of medicine undertaking the investigation of some special subject. In the new pathological laboratories ample provision is made for the teaching of the various branches of pathology and for the prosecution of original research. In the toxicological department there is a large laboratory, capable of accommodating fifty students, lighted from both sides and also from the roof, completely equipped with all that is necessary for the practical teaching of toxicology; also a small laboratory for private research, containing the apparatus and fittings necessary for investigations in toxicological chemistry. In the public health department suitable laboratory accommodation is provided for the study of sanitary chemistry, physics, and practical bacteriology in the departments of chemistry and physics and in that of pathology. A large room is provided in the new buildings for a museum of apparatus, models, plans, and other sanitary appliances for the practical instruction of the students, together with a special library of works on State medicine, hygiene, vital statistics, and sanitary engineering. In addition, a large lecture theatre for general purposes, accommodating 250 students, has been provided, and the existing accommodation for students is supplemented by the provision of a larger common room. The more strictly practical departments of medical study are taught partly in the Medical School and partly in the Royal Infirmary, to which are attached a fever hospital, a lunatic asylum, and a convalescent home. Medical and Surgical Clinical Classes are conducted in the infirmary, and separate instruction is afforded in the elements of Medical and Surgical Physical Diagnosis, in Obstetric Medicine, Ophthalmic Surgery, and Pathological Anatomy by the different members of the staff of the Medical School and Infirmary. The following entrance scholarships are offered for award to persons proposing to enter a medical course of study at the College:—Seaton.—One of £40, tenable for two years. Subjects: Greek and Latin Translation at sight, and Prose Composition. Credit given for knowledge of Mathematics (Geometry and Algebra); Elements of English Language, Literature, and History; French and German. Rogers.—One of £40, tenable for two years. Subjects as in Seaton. Dalton.—Two of £40, tenable for two years. Subjects: Geometry (Euclid I.—IV., and VI., or the subjects thereof); Algebra (as far as the Binomial Theorem, inclusive); Plane Trigonometry (to Solution of Triangles); Elementary Analytical Geometry; Conic Sections. Credit given for knowledge of Classics, Elements of English Language, Literature, and History; French and German. Hulme.—£35, tenable for three years. Subjects: English Language (Grammatical Structure and Outlines of its History); English Literature (an essay on some subject of English literature); and Modern History (Outlines of English History and Geography); with at least two of the following: Latin (Translation at sight, Grammar, and Easy Composition); Greek (ditto); French (ditto); German (ditto). Credit given for knowledge of Mathematics (Geometry and Algebra). James Gaskill.—£40, tenable for two years. Subjects: Mathematics, Geometry (the substance of Euclid I.—IV. and VI.), Algebra (as far as the Binomial Theorem, inclusive), Plane Trigonometry (to Solution of Triangles), Elementary Mechanics, Chemistry. Credit given for knowledge of Classics, Elements of English Language, Literature, and History, and French and German. Manchester Grammar School.—£18 per annum, tenable for three years. The examinations for all these scholarships are held in the month of June. A subject for an English Essay will also be set in each year. Kay-Shuttleworth (Sir James Phillips).—£30 per annum, tenable for three years. Examination in June. Subjects: Mathematics, Elementary Mechanics, Chemistry. Dauntesey Medical Scholarships.—Two Scholarships of £50 each are open to all students preparing for a medical course who shall not have attended lectures or Laboratory courses on human anatomy or physiology, or a purely medical or surgical course in the Owens College or any other Medical School in the United Kingdom. Candidates will be examined in Zoology, Botany, and Chemistry. Medals are awarded on the results of the various class examinations at the end of each session. A Platt Physiological Scholarship of £50 a year for two years is offered annually to the student who, having studied for one entire session in the Physiological Laboratory of Owens College, has prosecuted the best original investigation in Physiology and has passed a satisfactory examination in Physiology. Two Platt Exhibitions, of the value of £15 each, to be competed for by first and second year students in the class of Physiology. A Dumville Surgical Prize of £20 is offered annually for proficiency in Clinical Surgery. The Turner Medical Prize of £25 is awarded annually. The John Henry Agnew Scholarship in Diseases of Children (£30) is also offered for competition each year. Medical and Surgical Clinical Prizes, each of the value of 6 guineas, are open to competition each year for the best reports (with comments) of cases which have occurred in the wards of the infirmary.

MANCHESTER ROYAL INFIRMARY (300 beds).—Consulting Physicians: Drs. Frank Renaud, H. Browne, Sir Wm. Roberts, and Henry Simpson. Consulting Surgeons: Messrs. George Bowring, E. Lund, and F. A. Heath. Physicians: Drs. D. J. Leech, J. Dreschfeld, Graham Steell, and Thos. Harris. Assistant Physicians: Drs. J. S. Bury and A. T. Wilkinson. Consulting Obstetric Physician: Dr. Lloyd Roberts. Obstetric Physician: Dr. Archibald Donald. Surgeons: Messrs. Walter Whitehead, Thomas Jones, Jas. Hardie, and F. A. Southam. Assistant Surgeons: Messrs. G. A. Wright and Wm. Thorburn. Ophthalmic Surgeon: Dr. D. Little. Dental Surgeon: Mr. G. W. Smith. Medical Registrar: Dr. R. T. Williamson. Surgical Registrar: H. W. Pomfret, F.R.C.S. Administrators of Anæsthetics: Mr. Alexander Wilson and Mr. A. G. Andrews. General Superintendent and Secretary: Mr. W. L. Saunder.

BARNES CONVALESCENT HOSPITAL, Cheadle, Cheshire (in connexion with the Manchester Royal Infirmary; 136 beds).—Secretary: Mr. W. L. Saunder. Resident Medical Officer: Mr. F. H. Westmacott, F.R.C.S.

RADCLIFFE INFIRMARY, Oxford (120 beds).—This infirmary is open to students for Medical and Surgical work in the wards and out-patients' departments. Clinical lectures are given by the Lichfield Clinical Lecturers in Medicine and Surgery. Also tutorial instruction and demonstrations are given in special Regional Anatomy (medical and surgical), methods of Medical Diagnosis, and Surgical Manipulation. Demonstrations of Elementary Pathology are given in the post-mortem room and at the Pathological department of the museum. Practical Pharmacy is taught in the Infirmary Dispensary. The whole course of study at the museum and infirmary combined is intended for students until they have passed the Second Conjoint Examination or the First Oxford M.B.

SHEFFIELD SCHOOL OF MEDICINE.—An entrance scholarship of the value of £110 will be awarded to the best candidate (if of sufficient merit) in Mathematics, Elementary Physics, Inorganic Chemistry, Latin, and English. The examination will be held at Firth College on Sept. 26th and 27th. Applications to be sent to the school secretary not later than Sept. 19th. Prizes for Clinical Medicine and Surgery of 10 guineas are offered by the Clinical Committee. Prizes in books and certificates awarded annually. The medical school is provided with dissecting-room, physiological laboratory, museum, library, and class-rooms. The course of lectures and instruction is adapted to meet the requirements of the various examining bodies. Chemistry, Physics, Comparative Anatomy, Elementary Biology, Botany, and Toxicology are taken out at Firth College. The Sheffield General Infirmary contains 200 beds, including Ophthalmic and Dermatological departments, a museum of Pathology, library, and post-mortem theatre, with microscopes and all the appliances for clinical research. The Sheffield Royal Hospital contains 101 beds, and is recognised by the examining bodies. Perpetual fee for hospital practice £45 in one payment; or by two instalments: £26 on entering for hospital practice, and 22 guineas within twelve months afterwards. A tutor's fee of £2 2s. is required from students entering for Anatomy.

Digitized by Google

and Physiology. Students are also admitted to the practice of the Jessop Hospital for Diseases of Women, to the Borough Fever Hospitals, and the South Yorkshire Asylum.

JESSOP HOSPITAL FOR WOMEN, Gell-street, Sheffield.—The hospital is devoted to Diseases peculiar to Women. There is also an Obstetric Department for the admission of a small number of cases. A staff of midwives connected with the hospital attend lying-in women at their own homes, and, in case of need, are assisted by the members of the medical staff. Out-patients are attended daily. Students can attend the practice of the hospital and be supplied with cases of midwifery. Communications should be addressed to the Secretary, York Chambers, York-street, Sheffield.

ENGLISH PROVINCIAL HOSPITALS HAVING SPECIAL CLASSES AND FACILITIES FOR CLINICAL STUDY.

DEVON AND EXETER HOSPITAL, Exeter.—Medical and Surgical Staff: Consulting Physician: Dr. Drake. Physicians: Drs. H. Davy, Arthur G. Blomfield, and Wm. Gordon. Consulting Surgeons: Messrs. A. J. Cumming, T. W. Caird, and James Bankart. Surgeons: Messrs. J. D. Harris, E. J. Domville, Charles E. Bell, and A. C. Roper. House Surgeon: Mr. Henry Andrew. Assistant House Surgeon: Mr. H. H. Lloyd Patch. The hospital contains 218 beds (including special children's wards). There are a good library, museum, dissecting and post-mortem rooms. Attendance on the practice of this hospital qualifies for all the examining boards. Arrangements can be made by which students can attend Midwifery. There is also a Nurses' Home attached to the Hospital. For further particulars as to fees &c. apply to the House Surgeon.

WEST OF ENGLAND EYE INFIRMARY, Exeter.—Surgical Staff: Messrs. Bankart and Toeswill. Assistant Surgeon and Registrar: Mr. Roper. Secretary: Mr. R. C. Cole. The infirmary contains fifty beds. Students of the Exeter Hospital can attend the practice of the Eye Infirmary. Patients for the year ending Michaelmas, 1894, 2287. Total number of patients since the opening of the Infirmary in 1808, 85,673. Days of admission: Mondays, Tuesdays, and Fridays, at 11.

GENERAL KENT AND CANTERBURY HOSPITAL.—Opened for the reception of patients April 26th, 1793. 55,255 in-patients and 98,979 out-patients have been admitted since the hospital was opened. The hospital contains 106 beds. Pupils of the staff are admitted to the practice of the hospital, and have the use of the library of the East Kent and Canterbury Medical Society for £7 7s. Operation day, Thursday, 11 A.M. Physician: Dr. Henry Alex. Gogarty. Consulting Surgeons: Mr. James Reid and Mr. Charles Holttum. Surgeons: Messrs. Frank Wacher, T. Whitehead Reid, J. Greasley, and Sydney Wacher. Dentist: Mr. Martin L. Bell. House Surgeon: Mr. J. H. Joyce. Assistant House Surgeon: Mr. E. C. Frend. Secretary: Mr. Arthur J. Lancaster. Over 700 in-patients, 2000 out-patients and casualties, and 1000 dental cases are attended in a year.

LIVERPOOL NORTHERN HOSPITAL (160 beds).—There is a special ward for the treatment of children. Clinical lectures are delivered by the physicians and surgeons during the summer and winter sessions. Clinical clerkships and dresserships are open to all students without additional fee. Consulting Surgeons: Mr. W. H. Manifold and Dr. W. Macfie Campbell. Physicians: Dr. E. H. Dickinson, M.A.; Dr. James Barr. Surgeons: Messrs. Chauncy Puzey, Damer Harrisson, and A. H. Wilson. Fees for hospital attendance: Perpetual, £26 5s.; one year, £10 10s.; six months, £7 7s.; three months, £4 4s.; Practical Pharmacy, £2 2s. Students can enter to the medical or the surgical practice separately on payment of half the above fees.

LIVERPOOL ROYAL SOUTHERN HOSPITAL (CLINICAL SCHOOL).—Physicians: Dr. Cameron, Dr. Carter, and Dr. William Williams. Surgeons: Mr. Bawdon, Mr. Alexander, and Mr. Robert Jones. Ophthalmic Surgeon: Mr. Richard Williams. Aural Surgeon: Mr. Charles G. Lee. Dental Surgeon: Mr. Royston. Lecturer on Practical Medicine: Dr. Macalister. Surgical Tutor: Mr. Davey. Consulting Pathologist: Professor Boyce. Pathologist: Dr. Barendt. Medical Tutor and Bacteriologist: Dr. Hugh R. Jones. The hospital is situated within convenient distance of the School of Medicine and contains 200 beds. There are special wards for accidents and Diseases of Children, and there are also beds appropriated to the Diseases of Women. Clinical teaching is given in the hospital, and arrangements have been made to render it thorough and systematic. The members of the staff the wards daily, and clinical lectures are given every w Tutorial classes are also held each day at which the ju students are instructed in the methods of diagnosis and seniors are prepared for their final examinations. The p logical department has a good laboratory attached in w the students receive practical instruction. Recent bacteriological laboratory has been added, where stu are able to obtain a practical knowledge of bacteriolo relation to medicine. In connexion with the hospi course of instruction for gentlemen desirous of obtai diploma in Public Health is given, and with this obj chemical laboratory under Mr. Herbert Davies, M.A. Ca B Sc. Lond., has been opened. In addition to the clinical and post-mortem clerkships, which are open t students, the resident post of Ambulance Officer is awa every three months to the student whom the board consider most suited to hold it. A Scholarship of is competed for annually, which has attached to it clinical and pathological duties; and three prizes of £5 are yearly offered for the best series of clinical re Fees: Perpetual £26 5s.; one year £10 10s.; six months £ three months £4 4s. A limited number of resident p can be received. Terms (exclusive of fees for Ho Practice), £15 15s. per quarter. The practice of the ho is recognised by all examining bodies. For further ticulars apply to the Dean, Mr. Robert Jones, 11, N street, Liverpool.

ROYAL INFIRMARY, Liverpool. — The buildings o new Royal Infirmary were completed and occupied in They stand on the old site, adjacent to the college enlarged by the purchase of a fine frontage in Pem place and of the street known as Pembroke-ga Externally, they form a handsome and imposing gro buildings, the general arrangement of which ma gathered from the plan at the beginning of the prosp Every available open-air space has been taken advant to secure good airing grounds for the patients, an beauty of the buildings has been not a little enhan the numerous balconies, colonnades, and flat roofs a to the same purpose for both patients and re staff. Internally, no point in modern sanitary scien been omitted. There are 295 beds exclusive of the Hospital. The wards—some parallelograms, some circ have floors of waxed oak blocks laid on an iro cement substratum. Three operating theatres clinical lecture theatre have been provided. Th an electrical room, and provision for special kinds of The out-patient department comprises rooms for the ment and study of minor medical and surgical ma for diseases of the eye, skin, larynx, nose, and as well as a gynæcological department. There a Lock Hospital. A room has been allotted to the tutors, in which they may keep their records, whil surgeon and physician has a private room in con with his wards, where his dressers and clerks ma up and tabulate cases and investigate morbid pr The pathological department, which is daily becor more importance in medical education, has had muc expended upon it, so as to give proper facilities study of morbid anatomy. It is hoped that the f for clinical work will be such as not merely to ena present students to learn the practical parts of th fession thoroughly, but to attract students fron crowded institutions where the number of pupils i excess of the opportunities for the bedside study of In no hospital in the country are the resident ph and surgeons so comfortably lodged. Each is with a bedroom and a private sitting-room in add the music-room and dining-room, where all the sev dents meet in common. R. Caton, M.D., Secre Medical Board, 86, Rodney-street, Liverpool.

NORFOLK AND NORWICH HOSPITAL (220 beds). £10 10s. for six months', £15 15s. for twelve months' and surgical practice. Pupils: resident and non-r Consulting Physicians: Sir P. Eade, M.D., and Sir Bateman, M.D. Consulting Surgeon: Mr. W. F.R.C.S. Physicians: Dr. Barton and Dr. Burton-J Surgeons: Mr. Williams, Dr. Beverley, and Mr Robinson. Assistant Surgeons: Mr. S. H. Burton D. D. Day. Dental Surgeon: Mr. R. Wentworth House Surgeon: Mr. Reginald Crosse. Secretary: M Gabbett.

NORTHAMPTON GENERAL INFIRMARY (established 1743; rebuilt 1793).—In-patients, 1461; out-patients, 8673. The number of beds is 160. Out-pupils are received, and have every opportunity of acquiring a practical knowledge of their profession. Instruction is also given in Anatomy and Materia Medica and Practical Pharmacy. Non-resident pupils are taken at a fee of £10 10*s*.

NORTH STAFFORDSHIRE INFIRMARY AND EYE HOSPITAL, Hartshill, Stoke-on-Trent.—The New Infirmary, opened in 1869, is built on the pavilion plan, has accommodation for over 220 patients, including Children's wards, special Ovarian wards, and a special department for the treatment of Diseases of the Eye. In-patients last year, 1934; out-patients, 9783. The attendance of pupils at this infirmary is duly recognised by all the examining boards; and there are unusual facilities for acquiring a practical knowledge of the profession. Physicians: Dr. A. M. McAldowie and Dr. J. Charlesworth. Surgeons: Messrs. J. Alcock and W. D. Spanton. Ophthalmic Surgeon: Mr. Herbert Folker. Assistant Ophthalmic Surgeon: Mr. J. F. Arlidge. Assistant Physicians: Dr. S. King Alcock and Mr. H. Nicholls. Assistant Surgeons: Drs. G. S. Hatton and W. Hind. Dental Surgeon: Mr. A. Baines. House Physician: Mr. William C. Allardice. House Surgeon: Mr. John L. Sawers. Secretary: Mr. R Hordley, Hartshill, Stoke-on-Trent, from whom particulars as to fees, &c., may be obtained.

WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL (founded 1848; beds, 230).—A preparatory school of Medicine and Surgery. The pupils have the advantage of seeing the whole of the practice of the physicians and surgeons, and are trained in clinical work by the medical and surgical staff. The attendance of pupils at this hospital is recognised by all the examining boards. Operations are performed every Thursday at 11 o'clock.

SUSSEX COUNTY HOSPITAL (188 Beds).—During the year 1894, 1576 in-patients have been treated. The total number of out-patient attendances on the books during 1894 was 35,786. This hospital affords ample facilities for students, possessing a large out-patient department, a library, and a well-appointed museum. The hospital does not take resident pupils, but out-pupils may attend the practice of the hospital for any period not exceeding two years on payment in advance of such a fee, not exceeding 20 guineas, as the Committee of Management shall direct.

MANCHESTER GENERAL HOSPITAL FOR SICK CHILDREN, Pendlebury and Gartside-street.—The hospital contains 140 beds, including 28 for scarlet fever. The medical staff visit the hospital daily at 10 A.M. Clinical instruction is given by the medical staff at the Hospital and Dispensary. Out-patients are seen daily at 9 A.M. at the Dispensary, Gartside-street, Manchester. Physicians: Drs. Ashby and Hutton. Surgeon: Mr. G. A. Wright. Assistant Surgeon: Mr Joseph Collier. Resident Medical Officers: Dr. Carruthers and M. A. Byers, M.B. Medical Officer at the Dispensary: Mr. J. Hepworth, M.R.C.S. During 1894 there were 1284 in-patients, and 10,007 out-patients were under treatment at the Dispensary.

ROYAL PORTSMOUTH HOSPITAL.—One year's attendance recognised by the Examining Boards. Consulting Surgeon: Mr. K. E. Knight, M.R.C.S. Honorary Physicians: Edward J. Wallace, M.D., and J. Watson, M.D. Honorary Surgeons: J. Ward Cousins, M.D., F.R.C.S., A. Lloyd Owen, M.D., M.R.C.S., and H. Rundle, F.R.C.S. Gosport District: J. R. Kealy, M.D., E. T. Crouch, M.R.C.S. Dental Surgeon: W. H. Kirton, L.D.S.R.C.S.I. Medical Officer for Out-patients: C. H. Newby, F.R.C.S.

SCOTLAND.

MEDICAL SCHOOLS WITH FULL CURRICULUM.

EDINBURGH.

SCHOOL OF MEDICINE OF THE ROYAL COLLEGES, Edinburgh.—The students who enter the classes of the School of Medicine are students proceeding to University degrees; but also students who are intending to take other qualifications, such as the conjoint qualifications of the Royal College of Physicians of Edinburgh, the Royal College of Surgeons of Edinburgh, and the Faculty of Physicians and Surgeons of Glasgow, the Conjoint qualification of the Royal College of Physicians of London and the Royal College of Surgeons of England, and others. The number of students varies much in the classes and subjects. It is within the limit to say that some 1000 students avail themselves each year of the opportunity of attending the school. The lectures qualify for the University of Edinburgh and other Universities, the Royal Colleges of Physicians and Surgeons of Edinburgh, London, and Dublin, the Faculty of Physicians and Surgeons of Glasgow, and other Medical and Surgical and Public Boards. In accordance with the recent Statutes of the University of Edinburgh one half of the qualifying classes required for graduation may be attended in this school. The regulations require that the fee for any class, taken for Edinburgh University graduation, shall be the same as that for the corresponding class in the University. The whole education required for graduation at the University of London may be taken in this school.

Fees.—For a first course of lectures (Royal Colleges, &c.), £3 3*s*.; University Graduation, £4 4*s*.; for a second, £2 4*s*.; perpetual, £5 5*s*. To those who have already attended a first course in Edinburgh the perpetual fee is £2 4*s*. Practical Anatomy, with course of demonstrations, £4 4*s*. Practical Chemistry, £3 3*s*. Analytical Chemistry, £2 for one month, £5 for three months. Clinical Surgery and Clinical Medicine, each £3 5*s*. Practical Physiology, Practical Pathology, Practical Materia Medica and Pharmacy, Operative Surgery, Practical Medicine, Medical Diagnosis, Physics, and Biology, each £3 3*s*.; Diseases of the Ear and Throat, Diseases of the Skin, Diseases of the Chest, Diseases of Children, Diseases of the Eye, and Diseases of the Tropics and Climatology, each £2 2*s*. For summer courses of Clinical Surgery and Clinical Medicine, each £2 4*s*.; Practical Anatomy, including Anatomical Demonstrations, £2 2*s*.; Operative Surgery, £3 3*s*.; Insanity, £2 2*s*.; and Vaccination, £1 1*s*. Extra and senior classes are held in a number of branches of medical science which are beneficial to senior students and post-graduates.

The following order of study is recommended as a guide to the student for a five years' course, though not enjoined:—First Year: Biology, Physics, Anatomy, Practical Anatomy, Chemistry and Practical or Analytical Chemistry. Second Year: Anatomy, Practical Anatomy, Physiology, Practical Physiology, Surgery and Materia Medica—the last either in this or the third year—and Hospital. Third Year: Practice of Medicine, Clinical Surgery, Practical Pharmacy, Clinical Medicine, Pathology, and Hospital. Fourth Year: Surgery or Clinical Surgery, Midwifery and Diseases of Women and Children, Practice of Medicine or Clinical Medicine, Medical Jurisprudence, Practical Midwifery, Operative Surgery, and Hospital. Fifth Year: Classes on Special subjects, Hospital and Dispensary Practice.

SURGEONS' HALL, SCHOOL OF MEDICINE, Edinburgh.—At Surgeons' Hall, where the class-rooms of many of the lecturers are situated, lectures qualify for the University of Edinburgh and other Universities; the Royal Colleges of Physicians and Surgeons of Edinburgh, London, and Dublin; and other Medical and Public Boards.

In accordance with the statutes of the University of Edinburgh, one-half of the qualifying classes required for graduation may be attended in this school, in addition to the class of Practical Materia Medica and the classes of Clinical Medicine and Clinical Surgery. The regulations require that the fee for any class taken for graduation in Edinburgh shall be the same as that for the corresponding class in the University. The whole education required for graduation at the University of London may be taken in this school.

Fees.—For a First Course of Lectures, £3 5*s*.; for a Second, £2 4*s*.; Perpetual, £5 5*s*. To those who have already attended a First Course in Edinburgh the Perpetual Fee is £2 4*s*. Practical Anatomy (six months' course), £3 3*s*.; Course of Demonstrations, £2 2*s*.; Perpetual, £4 4*s*.; Practical Anatomy, with Course of Demonstrations, £4 4*s*.; Practical Chemistry, £3 3*s*.; Analytical Chemistry, £2 for one month, £5 for three months, or £10 for six months. Practical Physiology, Practical Pathology, and Practical Materia Medica and Pharmacy, each £3 3*s*. Diseases of the Ear and Throat and Diseases of the Eye, each £2 2*s*. For Summer Courses of Clinical Surgery and Clinical Medicine, each £2 4*s*.; Practical Anatomy, including Anatomical Demonstrations, £2 2*s*.; Operative Surgery, £3 3*s*. Insanity, £2 2*s*. The minimum cost of the education in this School of Medicine for the Triple Qualification of Physician and Surgeon from the Royal Colleges of Physicians and Surgeons

* Lectures, £3 5s.; Practical, £3 3s.; Analytical, £2 a month, or £5 for three months. † Also in Summer Session.
‡ Also in Winter Session. § Practical, £3 3s.; Analytical, £2 a month, or £5 for three months.
N.B.—Where two or more lecturers appear as teaching the same subjects, their lectures are not conjoined, but each gives an independent course.

of Edinburgh and the Faculty of Physicians and Surgeons of Glasgow, including the fees for the Joint Examinations, is about £100, which is payable by instalments during the period of study.

The following Order of Study is recommended as a guide to the student for a five years' course, though not enjoined:—First Year: Biology, Physics, Anatomy, Practical Anatomy, Chemistry, and Practical or Analytical Chemistry. Second Year: Anatomy, Practical Anatomy, Physiology, Practical Physiology, Surgery, and Materia Medica—the last either in this or the Third Year—and Hospital. Third Year: Practice of Medicine, Clinical Surgery, Practical Pharmacy, Clinical Medicine, Pathology, and Hospital. Fourth Year: Surgery or Clinical Surgery, Midwifery and Diseases of Women and Children, Practice of Medicine or Clinical Medicine, Medical Jurisprudence, Practical Midwifery, Operative Surgery, and Hospital. Fifth Year: Classes on Special Subjects, Hospital, and Dispensary Practice.

The appointment of Resident Physician to the wards in the Royal Infirmary under the care of the Ordinary Physicians is open to those members of their clinical class who have clerked in their wards for at least six months. Six Residentships

Digitized by Google

are appointed during the year for a period of six months each. Resident Surgeons are also appointed by the Ordinary Surgeons to the Hospital. In all respects the students are taught under regulations similar to those at the University of Edinburgh and the other Universities of Scotland, and they receive similar certificates at the close of each session. Moreover, the University College authorities in Edinburgh call upon each recognised lecturer to supply them at the close of each session with a statement giving the number of students attending the class, the number of lectures or prelections delivered during the session, the class examinations held, and the general mode of conducting the class. The courses on special non-qualifying subjects have for the last quarter of a century formed a marked feature of the school. Indeed, such medical subjects could be studied in Edinburgh only in this school until lately, when the University of Edinburgh appointed from the school, lecturers on Diseases of the Eye, Insanity, and Diseases of Children to take charge of classes intra-murally, and a tabular list of the classes and lecturers will be found above. The various classes in the school are conducted in several separate buildings (such as at Surgeons' Hall, Nicolson-street; Minto House, Chambers-street; Nicolson-square; New School, Bristo-street, &c.). Special courses of instruction for women students are also included in the curriculum of this school. Further particulars regarding the school will be found in the calendar, which will be forwarded *gratis* by the Secretary to the school, 24, Forrest-road, Edinburgh.

GLASGOW.

ANDERSON'S COLLEGE MEDICAL SCHOOL, Glasgow.—This medical school was founded in the year 1800. It has given twelve professors to the University of Glasgow, of whom four at present hold office. The following courses are given, which qualify for all the licensing boards and for the Universities of London, Durham, Ireland, Edinburgh, and Glasgow (the latter two under certain conditions):—In winter: Anatomy, Professor A. M. Buchanan, M.A., M.D.; Chemistry, Professor J. Robertson Watson, M.A.; Physics, Professor Peter Bennett; Zoology, Professor Geo. Bell Todd, M.B.; Physiology, Professor D. Campbell Black, M.D.; Surgery, Professor T. Kennedy Dalziel, M.B.; Practice of Medicine, Professor Samson Gemmell, M.D.; Midwifery and Diseases of Women and Children, Professor Wm. L. Reid, M.D.; Materia Medica, Professor R. Barclay Ness, M.A., M.B.; Ophthalmic Medicine and Surgery, T. Spence Meighan, M.D.; Aural Surgery, James Erskine, M.A., M.B.; Diseases of Throat and Nose, John Macintyre, M.B.; Hygiene and Public Health, Dr. J. Pearson Munro. In summer: Anatomy, Practical Anatomy and Osteology, Practical Chemistry, Physics, Zoology, Practical Materia Medica and Pharmacy, Practical Physiology, Operative Surgery, Medical Jurisprudence, Professor R. M. Buchanan, M.B.; Botany, Professor King; Ophthalmic Medicine and Surgery; Mental Diseases, Dr. Carswell; Hygiene and Public Health, and Aural Surgery. The Chemical Laboratory is open daily from 10 to 6. The Dissecting-room is open in winter from 9 A.M. to 6 P.M., and in summer from 6 A.M. to 6 P.M. The students are assisted in their dissections by the Professor and Demonstrators, by whom frequent examinations and demonstrations on the parts dissected are conducted. The supply of subjects for dissection is ample, and students are consequently provided with parts as soon as they may be ready for them. The Dissecting-room is provided with a complete series of dissected specimens, mounted in plaster-of-Paris, illustrating the anatomy of the human body. Candidates for the licence in Dental Surgery can obtain the full medical curriculum in Anatomy, Chemistry, Physiology, Surgery, Practice of Medicine, and Materia Medica. The courses special to Dentistry are conducted at the Glasgow Dental Hospital and School.

The new buildings are situated in Dumbarton-road, immediately to the west of the entrance to the Western Infirmary, within two minutes' walk of it, and four minutes' walk of the University. Extensive accommodation is provided for Practical Anatomy, Practical Chemistry, Practical Physiology, Practical Pharmacy, Public Health, and Operative Surgery. There are also provided a large library and reading-room, and a students' recreation-room.

Fees:—For each of the above courses of Lectures (Anatomy, Chemistry, and Biology excepted), first session, £2 2*s.*; second session, £1 1*s.* Anatomy Class Fees: Winter, first session (including Practical Anatomy), £4 4*s.*; second session (including Practical Anatomy), £4 4*s*; third session, £2 2*s.* To those who have had the necessary courses of Practical Anatomy the fee will be £1 1*s.* Summer, Lectures and Practical Anatomy, £2 12*s.* 6*d.*; Lectures alone, £1 11*s.* 6*d.*; Practical Anatomy alone, £1 1*s.*; Osteology and Practical Anatomy, £2 12*s.* 6*d.*; Osteology alone, £1 11*s* 6*d.* Chemistry Fees: First course, £2 2*s.*; second course, £2 2*s.* Biology fee (Botany and Zoology), £3 3*s.* Matriculation Fees: Winter, 10*s.* to those taking out two or more classes; 5*s.* to those taking out only one class. The fee of 10*s.* represents a combined fee for the winter and summer sessions. Summer, 5*s.*, except to those who have paid a fee of 10*s.* for the Winter Session. Students who have attended classes at other schools, and who desire to pursue their studies at Anderson's College Medical School, will be admitted to such classes as they may have attended elsewhere at the reduced fees.

Royal Infirmary.—Fees: Hospital Practice and Clinical Instruction, first year, £10 10*s.*; second year, £10 10*s.*; afterwards free. Six months, £6 6*s.*; three months, £4 4*s.*; Pathology, both courses, £3 3*s.* Vaccination Fee, £1 1*s.*

Western Infirmary.—Fees: Hospital Practice and Clinical Instruction, first year, £10 10*s.*; second year, £10 10*s.*; afterwards free. Six months, £7 7*s.*; three months, £4 4*s.* Pathology, first course, £3 3*s.*; second course, £2 2*s.* Practical Pathology, first course, £3 3*s.*, second course, £2 2*s.* Vaccination Fee, £1 1*s.*

Eye Infirmary.—Fee: Hospital Practice and Clinical instruction, six months, £1 1*s.*

Certificates of attendance on the lectures at Anderson's College Medical School are received by the Universities of London, Durham, Ireland, Edinburgh, and Glasgow (the latter two under certain conditions); by the Royal Colleges of Physicians of London and Edinburgh; by the Royal Colleges of Surgeons, England, Edinburgh, and Ireland; by the King and Queen's College of Physicians, Ireland; by the Faculty of Physicians and Surgeons of Glasgow; by the Apothecaries' Hall, London; and by the Army, Navy, and East India Boards. Communications relating to the Medical School to be addressed to the Secretary of the Medical Faculty, Professor A. M. Buchanan, M.A., M.D., Anderson's College Medical School, Dumbarton-road, Partick, Glasgow. Communications relating to the Preliminary Examination in General Education to be addressed to Alexander Mackay, Esq., LL.D., Educational Institute Office, 40, Princes-street, Edinburgh. Communications relating to the Triple Qualification to be addressed to Alexander Duncan, Esq., B.A., Faculty Hall, 242, St. Vincent-street, Glasgow. Communications relating to the Dental School to be addressed to D. M. Alexander, Esq., 97, West Regent-street, Glasgow.

At *Anderson's College Medical School* Professorships of Physics and Zoology and a Lectureship on Mental Diseases have been recently instituted. Lectures on Physics and on Zoology are delivered in winter and summer, and lectures on Mental Diseases in summer, the fee for Mental Diseases being £1 1*s.* The Kerr Bursary in Anatomy (value £10) is open to students of the Junior Anatomy Class during Winter Session 1895-96.

ST. MUNGO'S COLLEGE AND GLASGOW ROYAL INFIRMARY.—This College was incorporated in 1889. The Glasgow Royal Infirmary was founded in 1791. The Faculty of Medicine of the College occupies new buildings erected for the purposes of a medical school, adjoining and communicating with the Royal Infirmary. The Laboratories, Museums, and Lecture-rooms are equipped and adapted to modern scientific requirements. Recent additions consist of Public Health, Practical Zoology, and Bacteriological Laboratories. The Royal Infirmary, which is at the service of the College for the purpose of clinical and practical instruction, is one of the largest general and special hospitals in the kingdom. It has nearly 600 beds, and will almost immediately have considerably over 600. It has special wards for Diseases peculiar to Women, for Venereal Diseases, Erysipelas, Burns, and Diseases of the Throat and Nose. At the Dispensary special advice and treatment are given in diseases of the Eye, Ear, Teeth, and Skin, Women, Throat and Nose, in addition to the large and varied number of ordinary medical and surgical cases—over 37,000 per annum—which in a great industrial centre daily require attention. Students of the College and Hospital get the benefit of dispensary experience free of charge. All appointments are open. There are five Physicians' and seven Surgeons' Assistants, who board in the hospital free of charge and act in the capacity of House Physicians an

Digitized by Google

House Surgeons. These appointments are made for six months, and are open to gentlemen who have a legal qualification in Medicine or Surgery, and preference is given to the students of this College and Hospital. Clerks and Dressers are appointed by the Physicians and Surgeons. From the large number of cases of acute disease and accidents of varied character received into this hospital these appointments are very valuable. In the Pathological Department assistants are also appointed. The session will open with an address by Professor F. H. Napier on Wednesday, Oct. 23rd, at the College buildings.

Ophthalmic Department.—The Ophthalmic Institution in West Regent-street having been amalgamated with the Royal Infirmary, the usefulness of this department is very much increased, and greater opportunities are afforded to students for the practical study of Diseases of the Eye. Dr. Napier, the ophthalmic surgeon, attends the Royal Infirmary every Tuesday and Friday at 12 noon, and daily at the Institution in West Regent-street from 1 to 2 o'clock. Students can attend both without payment of any additional fee. Lectures are delivered twice a week during the winter and summer sessions. Fee for the course, £2 2*s.*

The fee for each class is £2 2*s.*, except for Anatomy, which is £4 4*s.*, Pathology £4 4*s.*, Zoology £4 4*s.*, Botany £3 3*s.*, and for Physics, which is £2 4*s.* 6*d.*, and certain extra classes, for which the fee is £1 1*s.* The governors have arranged a sessional fee, payment of which entitles the student to attendance not only on the curriculum classes, but all the classes—nearly as many more as the curriculum classes,—and this sessional fee is only slightly greater than the sum total of the fees required for the curriculum classes. Students are strongly recommended to begin their course on the sessional fee plan. This fee, exclusive of hospital practice, is £17 19*s.* 6*d.* for the first year, £15 15*s.* for the second, £10 10*s.* for the third, and £5 5*s.* for the fourth. The hospital fee (including clinical lectures) is £21 for a perpetual ticket. The classes in St. Mungo's College and in the Glasgow Royal Infirmary are for male students exclusively. Further particulars can be obtained in the Calendar of the College (price 1*s.*), which can be obtained on application to the Dean, Prof. R. T. Kent, 86 Castle-street, Glasgow. Remittance should accompany application.

GLASGOW WESTERN MEDICAL SCHOOL.—This School is situated in University-avenue, close to the University and Western Infirmary, in which latter students obtain their Hospital Practice and Clinical Lectures. Lectures and Demonstrations are given on Chemistry, on Anatomy, on Surgery, on Physiology, on Midwifery and Gynæcology, and on the Eye.

Class Fees.—For each course of Lectures the fee is £2 2*s.*, or in some cases £1 1*s.* There is no matriculation fee.

QUEEN MARGARET COLLEGE, University of Glasgow.—Queen Margaret College was founded in 1883 by the Glasgow Association for the Higher Education of Women (instituted in 1877), and handsome buildings and grounds near the University were presented to the College in 1884 by Mrs. John Elder. In 1890 a School of Medicine for women was added to its Arts Faculty. In 1892 when the Universities Commissioners issued an ordinance empowering the Scottish University Courts to make provision for the instruction of women, the Council of the College and Mrs. Elder transferred to the University the College, its buildings, grounds, and endowments, on condition that these should be devoted to the maintenance of University classes for women only. The College then became the women's department of the University of Glasgow; its classes are taught by professors of the University and other lecturers appointed by the University Court, and it is governed by the University Court and Senate. The curriculum, regulations, and fees are the same as those of the male students, and the University degrees are open to women on the same conditions as to men. They have access to the University Museum and can borrow books from the University Library, besides having a library of reference in Queen Margaret College. The number of students enrolled in session 1894–5 was 211, of whom 58 were studying medicine, and the rest arts or science. The School of Medicine is a special feature of the College and gives full preparation for the medical degrees. In July of last year, for the first time in the history of any Scottish university, women students graduated in medicine at the "capping" in Glasgow University. Excellent facilities for clinical work are given in the Royal Infirmary and other hospitals. By a gift of £5000 lately granted for the purpose by the Bellahouston Trust the University Court was enabled to add to the College a large new building for the study of Anatomy and Physiology, which it is expected will be opened next October. The Arthur Scholarship will be open in 1895 to students of the first year entered in October, 1894; and the Universities Commissioners have issued an ordinance making regulations for the admission of women to certain University bursaries, scholarships, and fellowships. A house of residence for students of the College coming from a distance was opened by the Queen Margaret Hall Co., Limited, in October of last year.

DUNDEE.

UNIVERSITY COLLEGE, Dundee. — The classes of this College have been specially recognised for purposes of graduation in Medicine and Science by the Universities of Glasgow and Edinburgh; they also qualify for the degrees of the University of London and the Royal University of Ireland and for the licences of the Royal Colleges. Equipment is provided for the first three years of the medical curriculum; and of recent years the laboratory accommodation in the departments of Chemistry, Botany, Zoology, Anatomy, and Physiology has been largely added to. The Royal Infirmary of Dundee contains about 300 beds, and the clinical instruction and hospital attendance in its wards are recognised by the various degree-giving and licensing bodies. The teaching staff of the school has lately been increased by the appointment of Lecturers on Medical Jurisprudence and Public Health, Mental Diseases, and Ophthalmology, and in these departments, as also in Operative Surgery and Practical Obstetrics, special facilities are offered to senior students.

Scholarships:—First year: (*a*) Three Armitstead Scholarships of £20 each, tenable for one year. (These Scholarships were founded and endowed in 1883 by George Armitstead, Esq., M.P.) (*b*) Three Scholarships of £15 each, tenable for one year. Second year: Three Armitstead Scholarships of £20 each, tenable for one year, to be awarded to day students entering upon their second year. Candidates must have attended not less than two regular courses at the College during the year immediately preceding the competition. (*c*) Bute Bursary, founded in 1893 by the Most Honourable the Marquess of Bute, K.T.; this bursary consists of the free proceeds of £1000. (*d*) Two bursaries of the annual value of £25, and tenable for three years, either "at University College, Dundee, or at any Scottish University."

Fees.—Chemistry, £3 3*s.*; Prof. P. F. Frankland, F.R.S. Practical Chemistry: Winter £3 3*s.*, Summer £2 2*s.*; Prof. P. F. Frankland, F.R.S. Physics: Winter £3 3*s.*, Summer £2 2*s.*; Prof. Steggall, M.A. Zoology, £3 3*s.* (including Practical Class); Prof. D'Arcy W. Thompson, M.A. Botany, £3 3*s.* (including Practical Class); Prof. Geddes. Anatomy, £3 3*s*; Prof. Paterson, M.D. Practical Anatomy: Winter £3 3*s.*, Summer £2 2*s*; Prof. Paterson, M.D. Physiology, £3 3*s.*; Prof. E. W. Reid, B.A., M.B. Practical Physiology and Histology, £2 2*s.*; Prof. E. W. Reid, B.A., M.B. Surgery, £2 2*s*; Dr. MacEwan. Operative Surgery, £3 3*s*; Dr. MacEwan. Clinical Medicine, Drs. Stalker and Mackie Whyte. Clinical Surgery, Drs. MacEwan and Templeman. Hospital fee, £2 2*s.*; Dispensary, £2 2*s.* The Lectures and Classes for the winter session will commence on Thursday, Oct. 10th.

ROYAL INFIRMARY.—The infirmary contains 286 beds, including a special ward for the Diseases of Children, Eye, and Lock cases. In addition, there were during last year 7523 out-patients and 5305 home patients. The Royal Infirmary offers exceptional facilities for practical work to students. Two qualified Resident Assistants and Clinical and Pathological Assistants are appointed as vacancies occur. Appointments: Two qualified Resident Medical Assistants are appointed annually. Clinical Clerks and Dressers are attached to the Physicians and Surgeons, and students are appointed as assistants in the Pathological department. There is in connexion with the hospital course a class of Minor Surgery and Bandaging, conducted by the Assistant Surgeon, and a class of Practical Pharmacy and Materia Medica held at the Dispensary. Full information can be obtained from Dr. Nathan Raw, Medical Superintendent.

ROYAL ASYLUM.—Clinical instruction is given at the Royal Asylum. Appointments: One paid qualified Resident Assistant and two unpaid Resident Clinical Assistants.

Digitized by Google

ABERDEEN.

ABERDEEN ROYAL LUNATIC ASYLUM.—Contains, with Agricultural Branch, about 720 beds. Medical Superintendent: Dr. William Reid. Assistant Physicians: Drs. C. Angus and J. F. Philip. Secretary: Mr. W. Carnie. Clinical instruction is given to students during three months in summer.

ABERDEEN ROYAL INFIRMARY.—Contains about 200 beds. Physicians: Drs. Argus Fraser and P. B. Smith, Professor Finlay, and Dr. James Rodger, Assistant Physician. Consulting Surgeon; Dr. J. C. O. Will. Surgeons: Professor A. Ogston, Drs. R. J. Garden and McK. Booth. Assistant Surgeons: Drs. J. S. Riddell, W. Sinclair, and J. Marnoch. Ophthalmic Surgeon: Dr. C. H. Usher. Pathologist: Professor David James Hamilton. Assistant Pathologist: Dr. George Dean. Dental Surgeon: Dr. Williamson. Chloroformist: Dr. G. M. Edmond. Medical Electrician: Dr. A. MacGregor. Treasurer and Secretary: Mr. W. Carnie.

INSTITUTIONS AFFORDING FACILITIES FOR CLINICAL OBSERVATION.

ROYAL INFIRMARY, Edinburgh.—Beds are set apart for clinical instruction by the professors of the University of Edinburgh. Courses of Clinical Medicine and Surgery are also given by the ordinary physicians and surgeons. Special instruction is given in the medical department on Diseases of Women, Physical Diagnosis, and on Diseases of the Skin; and in the surgical department on Diseases of the Eye, the Ear, the Larynx, and the Teeth. Separate wards are devoted to Venereal Diseases, Diseases of Women, Diseases of the Eye, the Ear, and the Skin, and also to cases of Incidental Delirium or Insanity. Three wards are specially set apart for Clinical Instruction to Women Students. Post-mortem examinations are conducted in the anatomical theatre by the pathologists, who also give practical instruction in Pathological Anatomy and Histology. The fees for hospital attendance are as follows—viz.: Perpetual ticket, in one payment, £12; annual ticket, £6 6s.; six months, £4 4s.; three months, £2 2s.; monthly, £1 1s. Separate payments amounting to £12 12s. entitle the student to a perpetual ticket. No fees are paid for any medical or surgical appointment. The appointments are as follows:—1. Resident physicians and surgeons are appointed, and live in the house free of charge. The appointment is for six months, but may be renewed at the end of that period by special recommendation. 2. Special non-resident clerks are appointed for six months. The appointment may be renewed for a like period by special recommendation. 3. Clerks and dressers are appointed by the physicians and surgeons. These appointments are open to all students and junior practitioners holding hospital tickets. 4. Assistants in the pathological department are appointed by the pathologists.

EDINBURGH EYE, EAR, AND THROAT INFIRMARY, 6, Cambridge-street, Lothian-road.—Clinical Lectures and Instruction are given in this institution, which is open at 1 o'clock daily for out-door patients for Eye Diseases; Mondays, Thursdays, and Saturdays at 12 noon for out-door Ear Patients; and Tuesdays and Fridays at 4 P.M. for out-door Throat Patients. Special Practical Ophthalmoscopic Classes by arrangement. Patients whose diseases require operations or more than ordinary care are accommodated in the house. Consulting Surgeon: Dr. Joseph Bell, F.R.C.S. Surgeons: Dr. J. J. Kirk Duncanson, F.R.C.P.E.; Dr. G. Hunter Mackenzie; Dr. William George Sym, F.R.C.S.E.; and Dr. Alexander Black, F.R.C.P.E. Dental Surgeon: Mr. G. W. Watson, L.D.S. Treasurer and Secretary: Mr. A. P. Purves, 12, Queen-street.

GLASGOW HOSPITAL AND DISPENSARY FOR DISEASES OF THE EAR, 28, Elmbank-crescent.—The hospital, which contains twelve beds for in-door patients, is always open for urgent cases. Hours of surgeons' visits 2 P.M. daily; clinical teaching daily. Out-patients are seen on Mondays, Tuesdays, Wednesdays, Thursdays, Fridays, and Saturdays, at 2 P.M., by Dr. Barr and assistants. Course of Lectures and Clinical Instruction given during winter months by Dr. Barr.

GLASGOW WESTERN INFIRMARY.—This hospital adjoins the University of Glasgow. Number of beds upwards of 400. Special wards are set apart for Diseases of Women and for Affections of the Skin. In the out-patient department there are special cliniques for Diseases of Women and for Diseases of the Throat, Ear, and Teeth. The Clinical Courses are given by the Physicians and Surgeons, each of whom conducts a separate class, and students require to enter their names at the beginning of the session for the class which they propose to attend. Special instruction is given to junior students by tutors or assistants, and clinical clerks and dressers are selected from the members of the class. All the courses of clinical instruction are recognised by the University of Glasgow and the other boards in the kingdom. In the Pathological Department the course is both systematic and practical, and extends through the winter and following summer; these are likewise recognised by the University for graduation. Nine resident assistants are appointed annually, without salary, from those who have completed their course. The fee for the hospital practice, including the various courses of clinical instruction, is 20 guineas in one payment, or in two equal instalments for the first and second year; for six months, 7 guineas; and for three months, 4 guineas.

ROYAL HOSPITAL FOR SICK CHILDREN, Glasgow, situated at Garnet Hill.—This hospital was opened in December, 1882, and is now available to medical students for clinical instruction in the diseases peculiar to childhood. The hospital includes 77 beds for non-infectious cases only. A specially designed Dispensary, or Out-patient Department, was opened in October, 1888. Students may be enrolled at any time. Fee £1 1s. Particulars on applying to the House Surgeon, 45, Scott-street, Garnet-hill, Glasgow.

GLASGOW OPHTHALMIC INSTITUTION, 126, West Regent-street (30 beds).—Clinical and systematic course of lectures for students during the winter and summer sessions. In-patients, 453; out- or dispensary patients, 8647. Operations on Tuesdays and Thursdays. Consulting Surgeon: D. N. Knox, M.B., C.M., F.F.P.S.G. Acting Surgeon: Francis H. Napier, M.B., B.S., F.R.C.S. Assistant Surgeon: A. T. Thomson, M.D. This institution has recently been amalgamated with the Glasgow Royal Infirmary, of which it forms an integral part.

GLASGOW EYE INFIRMARY, Berkeley-street and Charlotte-street.—This institution, the largest of its kind in Scotland, was founded in 1824. The Infirmary now consists of two large buildings—that in Berkeley-street being occupied as the Infirmary proper, and that in Charlotte-street (new buildings opened June, 1894) as a dispensary. The Infirmary is devoted exclusively to the treatment of Diseases of the Eye, and is intended primarily to provide treatment, and, when necessary, board and lodging, for those who are unable to do so for themselves. The average number of new patients for the last ten years has been 11,527, and the total number of cases treated in 1894 was 17,264. The Medical Staff is as follows:—Senior Surgeons: Thomas Reid, M.D. Surgeons: Thomas S. Meighan, M.D., A. Freeland Fergus, M.D., and A. Maitland Ramsay, M.D. Assistant Surgeons: William Robertson, M.B., C.M., Andrew Wilson, M.B., C.M., and James Hinshelwood, M.A., M.D. Pathologist: Leslie Buchanan, M.B., C.M. House Surgeon: Thomas D. Moffat, M.B., C.M. Assistant House Surgeon: William A. Kirkwood, M.B., C.M. Clinical Assistants: A. Lewis M'Millan, M.B., C.M.; William Weir, B.Sc., M.B., C.M.; Henry L. G. Leask, M.D.; W. Ernest Thomson, M.A., M.D.; and W. C. Murray, M.B., C.M.

Regulations as to Attendance of Students.—(1) Gentlemen may attend as students on payment to the treasurer of the following fees:—For six months £1 1s., twelve months £2 2s. (2) All students when duly entered in the Infirmary Register may attend the clinical instruction of any or every member of the medical staff on production of their tickets. The days on which the surgeons respectively attend to receive patients may be ascertained at the Infirmary. Students have the privilege of being present in the Dispensaries at such hours as are arranged. They may enter the wards along with the Surgeon whose clinique they are attending when he visits his patients. They may also be present at operations under the sanction of the surgeon operating, but no student may enter the wards or operating-room except under the aforesaid regulation. Students may be allowed the use of the journals and case-books for examination on applying to the House Surgeon. Secretary: William George Black, 88, West Regent-street.

IRISH SCHOOLS OF MEDICINE.

QUEEN'S COLLEGE SCHOOL OF MEDICINE, Belfast.—Eight Junior Scholarships have been founded in the Faculty of Medicine of the annual value of £25 each. Two are

tenable by matriculated students, of the first, second, third, and fourth years of their course respectively. The examinations for Junior Scholarships in the Faculty of Medicine take place at the commencement of the session. Matriculated students in Medicine intending to compete for Medical Scholarships of the second year must be of not more than one year's standing as students of Medicine, and must have attended, in some of the Queen's Colleges, or in a University capable of granting degrees in Medicine, two at least of the following courses—viz.: Chemistry, Botany and Zoology, Anatomy, Materia Medica, Practical Chemistry, and Physiology. Matriculated students in Medicine intending to compete for Medical Scholarships of the third year must be of two years' standing and not more, and must have attended, in some of the Queen's Colleges, or in a University capable of granting degrees in Medicine, four at least of the following courses—viz: Chemistry, Botany and Zoology, Anatomy, Materia Medica, Practical Chemistry, and Physiology. Matriculated students in Medicine intending to compete for Medical Scholarships of the fourth year must be of three years' standing and not more, and must, in addition to the qualifications prescribed above, have attended, in their third year, two at least of the following courses—viz: Theory and Practice of Medicine, Theory and Practice of Surgery, Midwifery, and Diseases of Women and Children.

QUEEN'S COLLEGE SCHOOL OF MEDICINE, Cork.—The building is provided with a very large, well-ventilated dissecting-room, with physiological and toxicological laboratories, materia medica, anatomical and pathological museums, as well as a room for surgical and obstetrical instruments and appliances. There are well-appointed physical and chemical laboratories, and a large natural history museum in the adjoining building, and part of the College ground is laid out as a botanical garden. The plant houses are now completed and well filled with plants, and are open to the students in the class of Botany.

Fees.—For Practical Anatomy and for Practical Chemistry, £3 each course; for Anatomy and Physiology, £3 first course, and £2 for each subsequent course. Other medical classes, £2 first course, and £1 each subsequent course. Eight scholarships (value about £30 each), as well as several exhibitions and class prizes, are awarded every year.

IRISH ANCILLARY MEDICAL SCHOOLS.

ADELAIDE MEDICAL AND SURGICAL HOSPITALS, Peter-street, Dublin.—Fee for nine months' hospital attendance, £12 12*s.*; six months, £8 8*s.* Summer, three months, £5 5*s.*

Staff.—Physicians: James Little, M.D., M.R.I.A., Wallace Beatty, M.D., F.R.C.P.I. Surgeons: Kendal Franks, M.D., F.R.C.S.I.; F. T. Heuston, M.D., F.R.C.S.I.; J. H. Scott, M.B., F.R.C.S.I. Obstetric Surgeon: R. D. Purefoy, M.B., F.R.C.S.I. Ophthalmic Surgeon: H. R. Swanzy, M.B., F.R.C.S.I. Assistant Physician: H. T. Bewley, M.D., F.R.C.P.I. Assistant Surgeon: T. E. Gordon, M.B. Pathologist and Bacteriologist: J. Alfred Scott, M.D., F.R.C.S.I. Medical and Surgical Registrar: G. Peacocke, M.B., B.Ch. House Surgeon: A. L'E. Orme, L.R.C.P., and L.R.C.S.I.

A resident surgeon is elected yearly, and three resident pupils half-yearly. At the termination of the session, prizes in Clinical Medicine and Surgery, and in Obstetric Medicine, will be awarded.

Hudson Scholarship.—In addition to the junior prizes, the Hudson Scholarship, £30 and a gold medal, as well as a prize of £10, together with a silver medal will be awarded at the end of the session for proficiency in Clinical Medicine and Medical Pathology, Clinical Surgery and Surgical Pathology, Pathological Histology, Surgical Appliances, including Instruments and Bandaging, Ophthalmology and Gynæcology.

The certificates of attendance are recognised by all the Universities and licensing bodies in the United Kingdom. Farther particulars may be obtained from Mr. F. T. Heuston.

COOMBE LYING-IN HOSPITAL AND GUINNESS DISPENSARY FOR THE TREATMENT OF DISEASES PECULIAR TO WOMEN, Dublin.—This hospital contains nearly 70 beds, and consists of two divisions, one of which is devoted to lying-in cases, and the other to the treatment of the diseases peculiar to women. The maternity department is one of the largest in Ireland, 3000 cases being annually treated either as intern or extern patients. A regular course of lectures is delivered in the hospital, and clinical instruction is given daily at the bedside. There are two large dispensaries connected with the institution, at one of which instruction is given on the General Diseases of Women and Children, and, in the other, on the Diseases peculiar to Women. There is accommodation for a limited number of intern pupils, who enjoy exceptional advantages of acquiring a practical knowledge of this branch of their profession. Two Resident Pupil Midwifery Assistants and one Clinical Clerk are elected half-yearly from among the pupils of the hospital. Certificates of attendance at this hospital are accepted by all licensing bodies, and the diploma is recognised by the Local Government Board as a full legal midwifery qualification. Fees (six months' course): extern pupils, 6 guineas, half payable in advance; intern pupils, 18 guineas for six months' residence. If pupils enter as interns by the month, the fees are £4 4*s.* for first month, and £3 3*s.* for each succeeding month. Intern pupils enjoy very special advantages, which can be learned on application. Registration fee on entrance, 10*s.* 6*d.* Students can enter for attendance at any time. Further particulars may be had on application to the Master or the Registrar at the hospital.

SIR PATRICK DUN'S HOSPITAL.—Fees for attendance of students—nine months, £12 12*s.*; six months, £8 8*s.*; three months, £5 5*s.* The hospital is open to extern students as well as to the students of Trinity College, and the certificates are recognised by all the licensing bodies in the kingdom. Dr. Ball, Secretary to the Medical Board, will give any further information.

MATER MISERICORDIÆ HOSPITAL, Dublin.—Consulting Physician: Dr. Francis R. Cruise. Physicians: Sir Christopher Nixon, Drs. Joseph Redmond, Michael Boyd, and John Murphy. Surgeons: Messrs. Patrick Hayes, Charles Coppinger, Arthur Chance, and John Lentaigne. Obstetric Physician: Dr. Thos. More Madden. Ophthalmic Surgeon: Mr. Louis Werner. Dental Surgeon: Mr. Daniel Corbett, jun. Pathologist: Dr. Edmond McWeeney. Anæsthetist: Dr. Michael O'Sullivan. House Physician: Dr. Alexander Blayney. House Surgeons: Messrs. William Dargan, Joseph O'Dwyer, Charles O'Gorman, and Hugh Kennedy. This hospital, the largest in Dublin, at present containing 323 beds, is open at all hours for the reception of accidents and urgent cases. Fifty beds are specially reserved for the reception of patients suffering from fever and other contagious diseases. Instruction at the bedside will be given by the Physicians and Surgeons at 9 A.M. daily. Clinical Instruction will commence on Tuesday, October 1st, at 9 o'clock A.M. A course of Clinical Instruction on Fever will be given during the winter and summer sessions. A certificate of attendance upon this course, to meet the requirements of the licensing bodies, may be obtained. Opportunities are afforded for the study of Diseases of Women in the ward under the care of the Obstetric Physician, and at the Dispensary held on Tuesdays and Saturdays. Ophthalmic Surgery will be taught in the Special Wards and Dispensary. Surgical Operations will be performed on Mondays, Tuesdays, Thursdays, and Saturdays at 10 o'clock. Connected with the hospital are extensive Dispensaries, which afford valuable opportunities for the study of general Medical and Surgical Diseases, Accidents, &c. Instruction will be given on Pathology and Bacteriology. Junior Appointments: A House Physician and four House Surgeons will be appointed annually. Eight resident pupils will be elected from the most attentive of the class to hold office for six months. For the current session the elections will take place in the first week of November and in the first week of May. Dressers and Clinical Clerks will be appointed, and certificates will be given to those who perform their duties to the satisfaction of the staff. Leonard Prizes: One Gold and one Silver Medal will be offered for competition annually in the subject of Medicine, and one Gold and one Silver Medal in the subject of Surgery. Junior Leonard Prizes: One prize value £3 and one prize value £2 will be awarded in Medicine, and one prize value £3 and one prize value £2 will be awarded in Surgery. They will be awarded on the aggregate of marks gained for Reports of Cases and at a Clinical Examination to be held at the close of the summer session. For further particulars see prospectus. Certificates of attendance upon this hospital are recognised by all the Universities and licensing bodies in the United Kingdom. Private Wards have been opened for the reception of Medical and Surgical cases. A Training Scho

Digitized by Google

and Home for Trained Nurses have been opened in connexion with the Hospital.

Terms of attendance.—Nine months, £12 12*s.*; six winter months, £8 8*s.*; three summer months, £5 5*s.* Entries can be made with any of the physicians or surgeons, or with the Registrar, Dr. Joseph Redmond, 8, Clare-street. A prospectus containing in detail the arrangements for Clinical Instruction, Prizes, &c., may be obtained from the Secretary, Arthur Chance, F.R.C.S., &c., 90, Merrion-square West, Dublin.

RICHMOND, WHITWORTH, AND HARDWICKE HOSPITALS, North Brunswick-street, Dublin.—These hospitals contain 312 beds—110 for Surgical cases, 82 for Medical cases, and 120 for Fever and other epidemic Diseases. A Resident Physician and a Resident Surgeon are appointed each year, and are paid for their services. Clinical Clerks: Ten Resident Clinical Clerks are appointed each half-year, and provided with furnished apartments, fuel, &c. These appointments are open not only to advanced Students as formerly, but also to those who are qualified in Medicine or Surgery. The Dressers are selected from among the best qualified of the pupils without the payment of any additional fee. For prospectuses apply to W. Thomson, F.R.C.S., Treasurer, 54, Stephen's-green East; or to Guy P. Nugent, M.D., Hon. Sec., 19 Lower Fitzwilliam-street, Dublin.

ROTUNDA HOSPITAL, Rutland-square, Dublin.—This institution consists of two distinct hospitals—namely, the Lying-in Hospital and the Auxiliary Hospital, the latter for the reception of patients suffering from Uterine and Ovarian Diseases. There is also a large extern maternity and a Dispensary for Diseases peculiar to Women, which is open daily. Clinical instruction is given daily (Saturdays excepted) in Midwifery and the Diseases peculiar to Women, special attention being directed to the application of antiseptics in Midwifery, and lectures on these subjects are delivered regularly throughout the session. Accommodation is provided for a limited number of intern pupils.

DR. STEEVENS'S HOSPITAL.—This hospital, containing beds for 200 patients, is situated close to the Kingsbridge Terminus of the Great Southern and Western Railway, occupying a position in the centre of one of the busiest manufacturing districts of the city, otherwise unprovided with medical institutions, and affords exceptional advantages for clinical instruction. Immediately adjoining is St. Patrick's (Swift's) Asylum for the Insane. The hospital is easily accessible by two lines of tramways. There is a ward entirely devoted to Syphilitic Disease, a detached building for Fever Cases, and an extensive Out-patient Department, with separate Clinics for Diseases of the Skin, Throat, Eye, Ear, and Teeth.

The hospital is visited daily at 9 A.M. by the physicians and surgeons. The surgical wards are also visited by the resident surgeon each evening. Clinical Lectures are given by the physicians and surgeons during the session. There is accommodation in the hospital for two medical and six surgical resident clinical assistants.

Fees.—Hospital Practice: Nine months, £12 12*s.*; six months, £8 8*s.*; three months, £5 5*s.* Dressership: £10 10*s.* each three months. Further information may be obtained from the Resident Surgeon or from R. A. Hayes, M.D., Hon. Sec., 82, Merrion-square South.

LONDON POST-GRADUATE COURSE.

THIS course is specially arranged to meet the wants of the practitioner and to enable him during his leisure time to brush up his knowledge on subjects about which he may desire further information. It has been both popular and successful and has been attended by men from all parts of the Empire, from all branches of the Services, from the United States of America, as well as from foreign countries. Members can enter for each or all of the courses of lectures for the term, for half the term, or for all the lectures for one week, and thus each can obtain just what he wants and in the shortest possible time. The Vacation Courses have been attended by large numbers of practitioners and have been much appreciated. By this means men who wished to bring themselves abreast of the scientific knowledge of the day have been able to learn the elements of the technique of bacteriology and the latest advances in hygiene in a fortnight's daily course. The staffs of the following hospitals have associated themselves for teaching purposes—viz., the Hospital for Sick Children, Great Ormond-street; the National Hospital for the Paralysed and the Epileptic, Queen-square; the Royal London Ophthalmic Hospital, Moorfields; the Hospital for Diseases of the Skin, Blackfriars; the London Throat Hospital; and the Bethlem Royal Hospital for Lunatics; and courses are given at the Bacteriological Laboratory, King's College, at the Parkes Museum on Hygiene, and at the Cleveland-street Sick Asylum on Clinical Medicine and Surgery. The fees are £1 1*s.* and £2 2*s.*, according to the number of lectures in the course. Further information can be obtained from, and fees should be paid to, Dr. Fletcher Little, Secretary, 32, Harley-street, Cavendish-square, W.

MEDICAL TEACHERS.

MR. J. BECKTON, assisted by his son, Mr. H. BECKTON, B.A. (Graduate in Honours, late Scholar of Clare College, Cambridge), prepares candidates for the London Matriculation, Medical and Law Preliminary, University Entrance, Local, 1st Conjoint, and other Examinations. The Mathematics and Physics for the D.P.H. coached by post. Boarders received.—19, Keppel-street, W.C.

Mr. A. H. DAWES, 1st B.A. Lond., prepares students for London Matriculation and all Medical and other Professional Preliminaries. Tuition privately, in small classes, or by post.—55 and 56, Chancery-lane, W.C.

Mr. JOHN T. SARLL, B.A. Lond. (for eighteen years with the late Mr. HENRY SERGEANT), holds special classes, morning and evening, for London University Matriculation, the Preliminary Medical Examinations, &c.—University Institute, 192, Euston-road.

Mr. R. C. B. KERIN, B.A. London, first in First Class Honours in Classics, assisted by a staff of B.A. and B.Sc. Honour Graduates, prepares candidates in class and by private Tuition for Medical Preliminaries, London Matriculation, Preliminary Scientific Inter. Science, Hospital Scholarships, &c. Chemical and Physical Laboratories. For last three years 61 London University Successes and 2 Hospital Science Scholarships, &c.—Carlyon College, 56 and 56, Chancery-lane, W.C.

Dr. MAYBURY, D.Sc. Lond., M.R.C.S., D.P.H. Dublin, L.S.A., A.R.S.M. & C., and Dr. Stokes, M.D. Brux., M.R.C.S., L.R.C.P., 453, Strand, or 19, Bloomsbury-square, London, prepare candidates for all Examinations in Medicine and Science.

The University Examination Postal Institution prepares candidates through the post or personally for all medical examinations. The four medical tutors have the M.D. or M.S. degree and are Medallists or Prize Men. Preparation also by the other tutors for the Preliminary Arts or Science Examinations. Laboratory for D.P.H. candidates. Numerous recent successes.—Apply to the Manager, Mr. E. S. Weymouth, M.A. Lond., Office, 27, Southampton-street, Strand, London, W.C.

M.D., B.S. Lond., M.R.C.P. Lond., prepares for all the Professional Exams. Small classes are held for the Final College of Surgeons and Physicians, the Hall, the M.D.'s of Brussels, Durham (fifteen years' standing), and St. Andrews. Tuition by correspondence.—Address, M.D., 23, Wimpole-street, Cavendish-square, W.

Laboratories have been set up and classes will be held to prepare pupils for the Prel. Sci., Inter. Sc., &c. Examinations. Private lessons to supplement the Hospital preparation for the above. Residence if desired. For terms, apply to Principal, Candidates' Laboratory, 18, Hogarth-road, Earl's-court.

Special preparation, in class, privately, and by correspondence, for the Triple Qualification, Edinburgh. Also for Fellowship Examinations of Royal College of Surgeons, Edinburgh, and M.D. Brussels. Resident pupils received.—Address, Class Rooms, 7, Chambers-street, Edinburgh.

Private coaching in Surgery and Medicine (clinical and museum work included), Anatomy and Physiology for all examinations by an M.D., M.R.C.P., on the Medical and an F.R.C.S. Eng. on the Surgical Teaching Staff of a London Hospital Medical School. Especial advantages for provincial men. Tuition by correspondence.—Tasma, THE LANCET Office, 423, Strand, W.C.

INSTRUCTORS IN ELOCUTION, &c.

Mr. H. N. DIXON, M.A. Lond. and Cambridge, F.L.S., gives a thorough and high-class Education to Deaf Children, based upon the Oral Method. Special arrangements made for very young children.—Apply, Wickham House, East Park Parade, Northampton. The school has recently been removed to new and enlarged premises in, however, the same situation.

Mr. WILLIAM VAN PRAAGH, the public introducer of the Pure Oral System of Teaching Deaf Mutes, has made the subject of Lip-reading and the cure of all Defects of Speech, both acquired and congenital, his special study. Papers on the various subjects can be had at 11, Fitzroy-square, W.

Professor ALTSCHUL, Ph.D., has made Stammering, Stuttering, Lisping, Falsetto, recent or of long standing, due to Nervousness, &c., irrespectively of age or sex (without any mechanical appliances), his special life-long study.—9, Old Bond-street, W.

Miss D'ORSEY (King's College), 162, Sloane-street, treats Defects of Voice. Principles of correct voice use at reduced fees to clergy, teachers, &c., in two visits. References permitted to specialists.

Mrs. EMIL BEHNKE gives instruction in Voice Training and treats Stammering and other Defects of Speech at 18, Earl's-court-square, W.C.

SCHOLARSHIPS GIVEN IN AID OF MEDICAL STUDY.

THE following list is as nearly complete as the Editors have been able to make it, and gives such prizes as would enter into a Student's calculation of the cost of Medical education. It does not contain prizes of less value than £10, or prizes of greater than this value which are given in any form except money or necessaries of medical study and research:—

INSTITUTION.	TITLE OF SCHOLARSHIP, &C.	ANNUAL OR TOTAL VALUE.	HOW LONG TENABLE.	HOW OBTAINABLE.	CONDITIONS ATTACHED TO TENURE.
OXFORD UNIVERSITY ..	Burdett-Coutts Scholarships.	£80 per annum.	2 years.	Competitive Examination.	....
	Radcliffe Trav. Fellowship.	£200 ,, ,,	3 years.	Ditto.	Foreign Travel for purpose of Medical Study.
	Rolleston Prize.	£60 ,, ,,	....	Original Research.	M.B. taken within 3 years.
LONDON UNIVERSITY ..	....	£40 per annum.	2 years.	By first place with distinction in ANATOMY at July Intermediate M.B. Examination.	Ditto.
		£40 per annum.	2 years.	By first place, with distinction in PHYSIOLOGY AND HISTOLOGY at July Intermediate M.B. Examination.	Ditto
		£30 per annum.	2 years.	By first place with distinction in ORGANIC CHEMISTRY at July Intermediate M.B. Examination.	Ditto.
		£30 per annum.	2 years.	By first place with distinction in MATERIA MEDICA and PHARMACEUTICAL CHEMISTRY at July Intermediate M.B. Examination.	Ditto.
	University Scholarship in Medicine.	£50 per annum.	2 years.	By first place with distinction in MEDICINE at M.B. Honours Examination.	
	University Scholarship in Obstetric Medicine.	£30 per annum.	2 years.	By first place with distinction in OBSTETRIC MEDICINE at M.B. Honours Examination.	
	University Scholarship in Forensic Medicine.	£30 per annum.	2 years.	By first place with distinction in FORENSIC MEDICINE at M.B. Honours Examination.	
	University Scholarship in Surgery.	£50 per annum.	2 years.	By first place with distinction in B.S. Honours Examination.

SCHOLARSHIPS GIVEN IN AID OF MEDICAL STUDY—continued.

INSTITUTION.	TITLE OF SCHOLARSHIP, &c.	ANNUAL OR TOTAL VALUE.	HOW LONG TENABLE.	HOW OBTAINABLE.	CONDITIONS ATTACHED TO TENURE.
CHARING-CROSS HOSPITAL AND COLLEGE	Entrance Scholarships, No. 1.	£120.	...	Open Competitive Examination in any three of the following groups of subjects: (1) ENGLISH, including LANGUAGE, HISTORY, and GEOGRAPHY; (2) ANY TWO of the following four Languages—LATIN, GREEK, FRENCH and GERMAN; (3) MATHEMATICS, including ARITHMETIC, ALGEBRA, and GEOMETRY, and MECHANICS, including STATICS and DYNAMICS; (4) INORGANIC CHEMISTRY and EXPERIMENTAL PHYSICS, including ACOUSTICS, HEAT, MAGNETISM, ELECTRICITY, and OPTICS; and (5) ANIMAL and VEGETABLE BIOLOGY.	Full Course at Charing-cross Hospital.
	,, No. 2.	£63.	....	Ditto.	Ditto.
	,, No. 3.	£63.	...	Competitive Examination in ANATOMY and PHYSIOLOGY, open to Students from the University of Oxford who have passed the First M.B. Examination, and to Students from the University of Cambridge who have passed the Second M.B. Examination, and who have not entered at any London Medical School.	Completion of Curriculum at Charing-cross Hospital.
	Llewellyn Scholarship.	£25.	...	Competitive Examination among Fourth-year Students in ANATOMY, PHYSIOLOGY, PHARMACOLOGY, MEDICINE, SURGERY, THERAPEUTICS, and MIDWIFERY.	None.
	Golding Scholarship.	£15.	...	Competitive Examination among Second-year General Students in DESCRIPTIVE ANATOMY, PHYSIOLOGY, CHEMISTRY, and BIOLOGY.	Students must have attended the Classes in each subject at this School.
ST. GEORGE'S HOSPITAL	Entrance Scholarships, No. 1.	£145.	...	Competitive Examination among First-year Students, being the sons of medical men, in LATIN, GREEK, FRENCH, GERMAN, MATHEMATICS, PHYSICS, CHEMISTRY, and PHYSIOGRAPHY; three at option.	Previous entrance at St. George's School.
	,, No. 2.	£85.	....	Competitive Examination among Students being First M.B.'s of Oxford and Second M.B.'s of Cambridge, in ORGANIC CHEMISTRY, ANATOMY, PHYSIOLOGY, ZOOLOGY, and BOTANY; two at option.	Ditto.
	,, No. 3.	£85.	....	Ditto.	Ditto.
	,, No. 4.	£85.	....	Competitive Examination among Students of Provincial University Colleges of similar standing in the same subjects.	None.
	,, No. 5.	£50.	...	Competitive Examination among Students in the same subjects as Entrance Scholarship No. 1.	Complete Course at St. George's School.
	,, No. 6.	£50.	....	Ditto.	Ditto.
	Wm. Brown Exhibition.	£100 per annum.	2 years.	Competitive Examination among Perpetual Students having registrable qualification in the PRACTICE OF MEDICINE, MIDWIFERY, and SURGERY.	None.
	,,	£40 per annum.	3 years.	Competition among Third-year Students in the same subjects.	None.
	Brackenbury Prize in Medicine.	Interest on £1103.	...	Competitive Examination among Students of not more than five years' standing.	None.
	Brackenbury Prize in Surgery.	Interest on £1103.	...	Competitive Examination among Students of not more than five years' standing.	None.
	Treasurer's Prize.	£10 10s.	...	Proficiency in Clinical Examination of three Medical and three Surgical Cases, together with a written Examination in Medicine, Surgery, and Midwifery.	None.
	H. C. Johnson Memorial Prize.	£10 10s.	...	Competitive Examination among Second-year Students in PRACTICAL ANATOMY.	None.
	Pollock Prize.	Interest on £372.	....	Competitive Examination among Second-year Students in PHYSIOLOGY, PHYSIOLOGICAL CHEMISTRY, and HISTOLOGY.	None.
	Clarke Prize.	Interest on £209.	....	Awarded for Clinical Work in the Hospital.	None.
	Thompson Medal.	Interest on £185.	...		
	Brodie Prize.	Interest on £220.	....		
	Acland Prize.	£5.	....		
	General Proficiency Prizes, No. 1.	£10 10s.	....	Competitive Examination among First-year Students in ELEMENTARY ANATOMY, BIOLOGY, CHEMISTRY, and MATERIA MEDICA.	None.
	,, No. 2.	£10 10s.	....	Competitive Examination among Second-year Students in ANATOMY, PHYSIOLOGY (including HISTOLOGY), and PHYSIOLOGICAL CHEMISTRY.

SCHOLARSHIPS GIVEN IN AID OF MEDICAL STUDY—*continued.*

INSTITUTION.	TITLE OF SCHOLARSHIP, &c.	ANNUAL OR TOTAL VALUE.	HOW LONG TENABLE.	HOW OBTAINABLE.	CONDITIONS ATTACHED TO TENURE.
ST. GEORGE'S HOSPITAL—*continued.*	General Proficiency Prizes. No. 3.	£10 10s.	....	Competitive Examination among Third-year Students in the PRINCIPLES and PRACTICE of MEDICINE and SURGERY, PATHOLOGY, and MIDWIFERY.	None.
GUY'S HOSPITAL..	Entrance Scholarships. No. 1.	£100.	....	Open Competitive Examination among Candidates under twenty years of age in LATIN, GREEK, FRENCH, GERMAN, ARITHMETIC, EUCLID, and ALGEBRA.	Course at Guy's Hospital.
	,, No. 2.	£50.	....	Under twenty-five years of age, ditto.	Ditto.
	,, No. 3.	£150.	....	Open Competitive Examination among Candidates under twenty-five years of age in INORGANIC CHEMISTRY, GENERAL BIOLOGY, and EXPERIMENTAL PHYSICS.	Perpetual Course at Guy's Hospital.
	,, No. 4.	£60.	....	Ditto.	Course at Guy's Hospital.
	Arthur Durham Prizes.	£5.	....	Dissections by First-year Students.	
		£15.	....	Dissections by Students of later years.	
	First Year's Prizes.	£50.	....	Competitive Examination among First-year Students in ANATOMY OF BONES, LIGAMENTS, and MUSCLES, PHYSIOLOGY, and CHEMISTRY.	None.
	,,	£25.	....	Ditto.	Ditto.
	Second Year's Prizes.	£25.	....	Competitive Examination among Second-year Students in ANATOMY, PHYSIOLOGY, and MATERIA MEDICA.	None.
	,,	£10.	....	Ditto.	Ditto.
	Michael Harris Prize.	£10.	....	Competitive Examination among Second-year Students in HUMAN ANATOMY.	Ditto.
	Sands Cox Scholarship.	£15 per annum.	3 years.	Competitive Examination among Second-year Students in PHYSIOLOGY, HISTOLOGY, and PHYSIOLOGICAL CHEMISTRY.	Course at Guy's Hospital.
	Third Year's Prizes.	£25.	....	Competitive Examination among Third-year Students in ANATOMY (Medical and Surgical), DIAGNOSIS, OPERATIVE and MINOR SURGERY, MIDWIFERY, and THERAPEUTICS.	None.
	,,	£10.	....	Ditto.	Ditto.
	Fourth Year's Prizes.	£25.	....	Competitive Examination among Fourth-year Students in MEDICINE, SURGERY, DISEASES OF WOMEN, and MEDICAL JURISPRUDENCE.	None.
	,,	£10.	....	Ditto.	Ditto.
	Golding Bird Prize.	£20 and Medal.	....	Competitive Examination among Fourth-year Students in DIAGNOSIS.	Ditto.
	Prize for Clinical Study.	£25.	....	ORIGINAL REPORTS on Three Medical and Three Surgical Cases.	None.
	Beaney Prize for Pathology.	£31 10s.	....	Competitive Examination among Students in PATHOLOGY.	Ditto.
	Beaney Scholarship for Materia Medica.	£31 10s. per annum.	....	For Research in MATERIA MEDICA.	Ditto.
	Gull Studentship.	£150 per annum.	3 years.	For Research in PATHOLOGY and allied subjects. *Not* awarded by Competitive Examination.	Study at Guy's Hospital.
KING'S COLLEGE	Warneford Scholarships. No. 1.	£25 per annum.	3 years.	Competitive Examination among Matriculated Medical Students in DIVINITY, ENGLISH, HISTORY, LATIN, GREEK, FRENCH, GERMAN, and MATHEMATICS.	Perpetual Course at King's College.
	,, No. 2.	£25 per annum.	3 years.	Ditto.	Ditto.
	,, No. 3.	£25 per annum.	2 years.	Ditto.	Ditto.
	,, Class II.	£25 per annum.	2 years.	Competitive Examination among Matriculated Medical Students in the third year, residing in the College.	
	Sambrooke Exhibitions. No. 1.	£60.	....	Competitive Examination among Matriculated Students in MATHEMATICS, ELEMENTARY PHYSICS, INORGANIC CHEMISTRY, BOTANY, and ZOOLOGY.	Course either as Science or Medical Student at King's College.
	,, No. 2.	£40.	....	Ditto.	Ditto.
	Rabbeth Scholarship.	£20.	....	Competitive Examination among Matriculated Students in Science.	None.
	Science Exhibitions. No. 1.	£30 per annum.	2 years.	Competitive Examination among Candidates under nineteen years of age in MATHEMATICS, MECHANICS, PHYSICS, &c., or alternative Subjects.	None.
	,, No. 2.	£20 per annum.	2 years.	Ditto.	None.
	Medical Scholarships. No. 1.	£40 per annum.	2 years.	Competitive Examination among Third- and Fourth-year Students.	
	,, No. 2.	£30.	1 year.	Competitive Examination among Second- and Third-year Students.	
	,, No. 3.	£20.	1 year.	Competitive Examination among First-year Medical Students.	
	,, No. 4.	£20.	1 year.	Ditto.	
	,, No. 5.	£20.	1 year.	Ditto.	
	Sambrooke Registrarship. No. 1.	£50.	2 years.	Competitive Examination among Matriculated Medical Students who have filled certain appointments at hospitals.	
	,, No. 2.	£50.	....	Ditto.	
	Daniel Scholarship.	£20 per annum.	2 years.	Open Competitive Examination among six months' Laboratory Students.	
	Carter Prize.	£15.	....	Open Competitive Examination in Botany.

	Infirmary Scholarship.	£42.	...	Competitive Examination in ARTS among Students who have passed one of the Preliminary Examinations.	Complete Course of Hospital Practice and Clinical Lectures at Leeds Infirmary.
	Hardwick Prize.	£10.	...	Competitive Examination among Clinical Clerk Students of two years' standing in CLINICAL MEDICINE.	
	McGill Prize.	£10.	....	Competitive Examination among advanced Surgical Students in CLINICAL SURGERY.	
	Thorp Prizes.	£10 and £5.	....	Examinations in Forensic Medicine and Hygiene.	
	Thorp Prize Essay.	£15.	...	Essay or research on some subject connected with FORENSIC MEDICINE, TOXICOLOGY, or PUBLIC HEALTH.	Every three years to former students of the Leeds School.
UNIVERSITY COLLEGE, LIVERPOOL.	Holt Tutorial Scholarships (two annually).	£100 each.	1 year.	Vote of Faculty to Student of not less than four years' standing.	Teaching and Original Research.
	Lyon Jones Scholarship. No. 1.	£21 per annum.	2 years.	Competitive Examination among Junior Students in 1st M.B. SUBJECTS.	Perpetual Course at Victoria University.
	,, No. 2.	£21.	....	Competitive Examination among Third-year Students in ANATOMY, PHYSIOLOGY, and MATERIA MEDICA.	
	Derby Exhibition.	£15.	...	Competitive Examination among Fourth- or Fifth-year Students in CLINICAL SUBJECTS.	

PUBLIC HEALTH.

INSTRUCTION FOR DIPLOMAS IN STATE MEDICINE.

ENGLAND.

THE following recommendations, designed with a view of ensuring "the possession of a distinctively high proficiency, scientific and practical, in all the branches of study which concern the public health," were adopted by the General Medical Council in 1889. The regulations require that—"(1) A period of not less than twelve months shall elapse between the attainment of a first registrable qualification in Medicine, Surgery, and Midwifery and the examination for a diploma in Sanitary Science, Public Health, or State Medicine; (2) every candidate shall have produced evidence of having attended, after obtaining a registrable qualification, during a period of six months, practical instruction in a laboratory approved of by the body granting the qualification; (3) every candidate shall have produced evidence of having for six months practically studied the duties of out-door sanitary work under the medical officer of health of a county or large urban district; (4) the examination shall have been conducted by examiners specially qualified, and shall comprise laboratory work as well as written and oral examination; (5) the rules as to study shall not apply to—(*a*) medical practitioners registered, or entitled to be registered, on or before Jan. 1st, 1890." It was enacted by Section 18 (2) of the Local Government Act, 1888, that after Jan. 1st, 1892, no such appointment (that of medical officer of health) may be made in any county, or in any district or combination of districts with a population of 50 000 or upwards, unless the officer—having, of course, qualifications in Medicine, Surgery, and Midwifery—is registered as

the holder of a diploma in Sanitary Science, Public Health, or State Medicine under Section 21 of the Medical Act, 1886, or has during any three consecutive years preceding 1892 been medical officer of a district or combination of districts with a population of 20,000 at least, or has for three years previous to Aug. 13th, 1886, been a medical officer or inspector of the Local Government Board. With the sanction of the Local Government Board, the same person may be appointed medical officer for two or more districts.

London University.—Sanitary Science is included under the head of State Medicine in the M.D. degree, and a certificate has to be produced showing that a course of practical instruction has been attended for the prescribed period, and that the course has included such chemical, microscopical, and meteorological work and exercises as more especially relate to sanitation. The attendance includes six months' practical instruction in a laboratory and six months' out-door sanitary work. Certificates will be received from the holder of any public health office directly or indirectly subject to control by a Secretary of State or a Government Department. If a candidate have held for a period of two years the position of medical officer of health in any sanitary district, or for a period of three years the position of medical officer of health in any sanitary district, he will be eligible for the examination.

Cambridge University.—An Examination in so much of State Medicine as is comprised in the functions of medical officers of health will be held during the year 1894 in Cambridge, beginning on the first Tuesday in October, and ending on the following Friday, or at latest on the following Saturday. Any person whose name is on the Medical Register is eligible as a candidate for this examination: Provided (*a*) he be in his twenty-fourth year at least when he presents himself for the first part of the examination, and have attained twenty-four years of age before he presents himself for the second part; (*b*) a period of not less than twelve months shall have elapsed between the time when he first obtained a registrable qualification and the time when he presents himself for either part of the examination; (*c*) he produce evidence of having, before or after obtaining a registrable qualification, attended the clinical practice of a hospital for infectious diseases approved by one of the licensing bodies recognised under the Medical Acts; (*d*) he produce evidence of having, after obtaining a registrable qualification, attended during a period of six months on one or more courses, approved by the Syndicate, of practical laboratory instruction in Chemistry, Bacteriology, and the Pathology of those diseases of animals that are transmissible to man; (*e*) he produce evidence of having, after obtaining a registrable qualification, practically studied for six months the duties of out-door sanitary work under the medical officer of health of a county or large urban district, unless he have himself held an appointment as medical officer of health under conditions not requiring a special sanitary diploma. The provisions (*b*), (*c*), (*d*), (*e*) are not to apply to (*a*) candidates whose names shall have been placed on the Medical Register on or before Jan. 1st, 1890, or who have obtained a registrable qualification on or before that date; (*β*) candidates who have for a period of three years held the position of medical officer of health to any county, or to any urban district of more than 20,000 inhabitants, or to any entire rural sanitary district. The examination will be in two parts. The first part will comprise Physics and Chemistry; the principles of chemistry and methods of analysis, with especial reference to analyses of air, water, and food; application of the microscope, including the investigation of micro-organisms; the laws of heat and the principles of pneumatics, hydrostatics, and hydraulics, with especial reference to ventilation, water-supply, drainage, construction of dwellings, disposal of sewage and refuse, and sanitary engineering in general; meteorology in relation to health; sources of water-supply; and statistical methods in their application to public health. The second part will comprise Laws and Statutes relating to public health; origin, propagation, pathology, and prevention of epidemic and infectious diseases, including those diseases of animals that are transmissible to man; effects of overcrowding, vitiated air, impure water, and bad or insufficient food; unhealthy occupations and the diseases to which they give rise; water-supply and drainage in reference to health; nuisances injurious to health; distribution of diseases within the United Kingdom, and effects of soil, season, and climate. The following is a list of Colleges and Schools of Medicine at which the courses of laboratory instruction have, for the purposes of this examination, been already approved by the Syndicate: The Chemical Laboratory, Cambridge; the London Hospital Medical College; St. Bartholomew's Hospital Medical College; King's College, London; University College, London; the Army Medical School, Netley; Owens College, Manchester; the University of Durham Medical School, Newcastle-on-Tyne; Mason College, Birmingham; University College, Liverpool; St. Mary's Hospital Medical College; Charing-cross Hospital College; University College, Bristol; and Yorkshire College, Leeds. The examination in both parts will be oral and practical, as well as in writing. One day at least will be devoted to practical laboratory work, and one day to oral and practical examination in, and reporting on, subjects connected with out-door sanitary work. Every candidate will be required to pay a fee of £5 5*s.* before admission or readmission to *either part* of the examination. Every candidate who has passed both parts of the examination to the satisfaction of the examiners will receive a diploma testifying to his competent knowledge of what is required for the duties of a medical officer of health. All applications for information respecting this examination should be addressed to Dr. Anningson, Barton-road, Cambridge, Secretary to the Syndicate. Candidates who desire to present themselves for the examination in October next must send in their applications on forms supplied for the purpose and transmit the fees to J. W. Clark, M.A., Registrary, University of Cambridge, on or before Sept. 17th. Cheques should be crossed "Mortlock and Co., Ltd." The fee for either part of the examination cannot be returned to any candidate who fails to present himself; but he will be entitled, without an additional fee, to be a candidate on one subsequent occasion. The applications of candidates whose names have not been on the Medical Register for three years should be accompanied by a certificate of birth or other proof of age.

University of Oxford.—An examination, open at present to those only who have obtained the degree of M.B. in the University of Oxford, conducted partly in writing, partly *viva voce*, and in each subject partly practical, is held in Michaelmas Term in the following subjects:—General Pathology, with special relation to Infectious Diseases, the Laws relating to Public Health, Sanitary Engineering, Vital Statistics. The fee for admission to the examination is £10. Candidates (*a*) must have their names on the Medical Register of the United Kingdom; (*b*) must have spent after registration a period of at least six months studying in a public health laboratory approved by the Board of the Faculty of Medicine. Candidates must also (*c*) have had their names on the Medical Register of the United Kingdom for a period of at least twelve months; (*d*) have spent after registration a period of study, of not less than six months in all, under the medical officer of health of a county or of a city or town containing at least 50,000 inhabitants, or under two or more such medical officers of health. Certificates of proficiency are granted to those who pass this examination.

University of Durham.—Sanitary Science is the special object of the degrees in Hygiene. Candidates for the degree of Bachelor in Hygiene (B.Hy.) must be at least twenty-two years of age and registered, and before presenting themselves for examination must have been for at least twelve months graduates in Medicine of a recognised university. They shall spend six months at Newcastle-upon-Tyne studying Public Health, Comparative Pathology, Practical Bacteriology, Outdoor Sanitary Work, Infectious Diseases, Sanitary and Practical Chemistry. They have to pass an examination in Sanitary Chemistry, Physics, Sanitary Legislation, Comparative Pathology, Vital Statistics, Nosology, Distribution of Health and Disease, Sanitary Medicine, and Practical Hygiene. The fee for the examination for the degree of B.Hy. is 10 guineas, and for the degree £6. Candidates for the degree of Doctor in Hygiene (D.Hy.) must have acquired the degree of Bachelor in Hygiene, must for two years subsequently have been engaged in practice as a Medical Officer of Health, and must write an essay upon some practical hygienic subject. The fee for the examination for the degree of D.Hy. is £5, and for the degree £6. The regulations for education and examination for the Diploma in Public Health (D.P.H.) are the same as those for the degree of Bachelor of Hygiene, except that the candidate is not required to be a graduate in Medicine of a recognised university, and the course of study need not be passed at Newcastle-upon-Tyne. The fee for the examination and diploma in Public Health is ten guineas.

Digitized by Google

Victoria University.—An examination in Sanitary Science is held yearly, beginning about the middle of July, under the following regulations: The examination is in two parts, and is written, oral, and practical. Candidates before entering for either part of the examination must have held for not less than twelve months a registrable qualification in Medicine, Surgery, and Midwifery, and must present satisfactory certificates of having attended courses of instruction in Public Health and in Chemistry as applied to Public Health in a college of the University, or in a college or medical school recognised for this purpose by the University; of having attended, after obtaining a registrable qualification, during at least six months, practical instruction in a laboratory approved by the University; of having practically studied the duties of out-door sanitary work for not less than six months under the Medical Officer of Health of a county or of a large urban district. Candidates may present themselves for Parts I. and II. separately or at the same time, provided that no candidate be admitted to Part II. unless he has already presented himself for Part I. No candidate's name will be published until he has satisfied the examiners in both parts of the examination. The fee for each part is £4 4*s.*, and must be paid on or before July 1st in each year. For any subsequent examination in the same part the fee will be £2 2*s.* Every candidate who has passed both parts of the examination to the satisfaction of the examiners, and who is legally registered, will receive a diploma in Sanitary Science. The examinations will begin on the third Monday in July each year.

Royal College of Physicians of London and the Royal College of Surgeons of England.—The following are the regulations for obtaining the diploma in Public Health: Section 1: Candidates must be registered under the Medical Act. The examination consists of two parts. The fee for each part is £5 5*s.* A candidate intending to present himself must give fourteen days' written notice to the Secretary, at the Examination Hall, Thames Embankment, W.C. A candidate registered under the Medical Act on or before Jan. 1st, 1890, will be admissible to Part I. of the examination on producing evidence of being at least twenty-three years of age, and to Part II. on producing evidence of being at least twenty-four years of age. A candidate registered under the Medical Act after Jan. 1st, 1890, will be admissible to examination in Part I. on producing evidence (1) of having been in possession of a registrable qualification in Medicine, Surgery, and Midwifery for at least twelve months; (2) of having attended, after obtaining such registrable qualification, practical instruction in a laboratory recognised by the Examining Board in England during a period of six months; and (3) of being at least twenty-three years of age. A candidate will be admitted to Part II. of the examination on producing evidence (1) of having, during a period of six months after obtaining a registrable qualification, either practically studied the duties of out-door Sanitary Work under the medical officer of health of a county or large urban district or else held appointment as medical officer of health under conditions not requiring the possession of a special Sanitary diploma; (2) of having attended the clinical practice of a hospital for infectious diseases recognised by the Examining Board in England, either before or after obtaining his registrable qualification in Medicine, Surgery, and Midwifery (this certificate is not required in the case of a candidate who produces evidence that he has commenced special study of Sanitary Science before Jan 1st, 1894); and (3) of being at least twenty-four years of age.

King's College, London.—A course of lectures will be given in the summer session by Professor Charles Kelly, M.D., F.R.C.P. Practical instruction will be given in the uses of Sanitary Appliances at the Parkes' Museum, Margaret-street, Regent-street, W. The lectures will be given during the summer session on Thursdays at 12.30 P.M. Fee for the course, £2 2*s.*, payable in advance in the College Office. Medical students at King's College, free. The necessary Laboratory Instruction to comply with the regulations of the various Universities and other Medical Licensing Bodies will be given by Professor William R. Smith, M.D., D.Sc., and Professor Edgar M. Crookshank, M.B. Lond. The syllabus includes Physics, Chemistry, Microscopy; Parasites and other Organisms Infesting Food-stuff or the Human Body; Bacteriology, including the Cultivation and Recognition of Micro-organisms. The course will last six months, four months of which will be spent in the Laboratories of Public Health, and two months in the Bacteriological Laboratory. Fee 20 guineas, payable in advance in the College Office. Under the direction of Professor William R. Smith, M.D., D.Sc., and Demonstrator, C. G. Moor, M.A., practical instruction will be given in the laboratories in the methods of Analysis of Air, Water, Foods, &c.; Detection of Poisons. Fees, one month, £4 4*s.*; three months, £10 10*s.* The laboratories are also available for original investigations and practical work in Public Health, and are open daily from 9 A.M. to 4 P.M. and on Saturdays to 1 P.M. In Public Health special classes will be held during the winter session by Professor W. R. Smith; fee, £12 12*s.* The Bacteriological Laboratory is open daily for original research under the direction of the professor and demonstrator of Comparative Pathology and Bacteriology. For one month for original research, 3 guineas. For a longer period by arrangement. For one month for private study, with supervision 4 guineas. For a longer period by arrangement. Practical course for a month, with attendance on lectures, 5 guineas. For a year, 30 guineas. Professor H. G. Seeley, F.R.S. will deliver a course of six lectures on Physiography. For further particulars connected with any of the foregoing classes apply to Professor W. R. Smith, King's College, London.

University College, Bristol.—A course of lectures on Principles and Practice of Hygiene is given at the Medical School, Bristol, by D. S. Davies, M.B.Lond., D.P.H. Cant. on Mondays and Fridays, 10–11 A.M., commencing on the first Monday in October. A six months' course of Practical Laboratory Instruction is given at the Western Counties Laboratory, Park-street, by Mr. F. Wallis Stoddart, commencing on the first Wednesday in October, and including the subjects of Chemistry, Physics, Bacteriology, and Deposites. Demonstrations on the provisions and practical working of the various Acts relating to Public Health and of Orders, Circulars, and By-laws of the Local Government Board are delivered by Mr. J. C. Heaven on Mondays and Fridays, commencing on the first Monday in October. Gentlemen taking out the course are admitted to practise out-door sanitary work during the session, under the supervision of the Medical Officer of Health for the city and port of Bristol. They are considered as pupil assistants, are required to carry out diligently such of the duties of medical officers of health as they may be directed to undertake. Facilities are afforded during the course for the study of those diseases of the lower animals which are communicable to man. Fee for the entire course, 20 guineas.

SCOTLAND.

Edinburgh University.—Two degrees in Science in the Department of Public Health are conferred by the University of Edinburgh—viz., Bachelor of Science (B.Sc.) and Doctor of Science (D.Sc.). Every candidate who desires to proceed to the first examination for the degree of B.Sc. must give evidence that he has taken a degree in Medicine in the University of Edinburgh or in a recognised University, and that he has worked for at least six months during the usual winter session, in a laboratory where practical instruction is given in the methods of investigation in subjects pertaining to Public Health. Laboratory work recognised in which provision is not made for the study of Public Health laboratory in accordance with the regulations for laboratory work issued by the Senatus, nor will time be recognised if such work is not taught by a specially appointed teacher. Candidates will not be admitted to the First Examination for the said degree until one year after taking a degree in Medicine, nor until an interval of at least six months has elapsed after passing the First Examination. Two laboratories are entirely devoted to Public Health, and the demonstrator teaches in them from 10 A.M. to 4 P.M. daily. The teaching is both individual and by means of groups of students. The latter are given twice a week, and deal with the *rationale* of the methods employed in practical work.

Bachelors of Science in the department of Public Health may, after the lapse of one year, proceed to the degree of Doctor in the same department, on producing evidence that they have been engaged in Practical Sanitation since they took the said degree of Bachelor of Science, and on presenting a Thesis on some subject in the department of Public Health. For the First Examination for the degree of Doctor the fee is £5 5*s.*, and for the Second Examination for the degree of Doctor, £5 5*s.*; fee for registration as a member of the University Council (unless previously registered), £1. New regulations, however, are in preparation.

Digitized by Google

Glasgow University.—The University provides instruction in Public Health by laboratory training and otherwise. The subjects of instruction are:—Duties of health officer, air and ventilation, food and its adulterations, water and water-supply, sewerage and drainage; construction of hospitals, public buildings, and dwellings; overcrowding, manufactories, insalubrious trades, cemeteries, nuisances, quarantine, disinfectants and deodorisers, outbreaks of zymotic diseases; climate, topographical and seasonal; its influences in relation to health and disease; geographical distribution of diseases; knowledge of leading Sanitary Acts of Parliament; vital statistics. The laboratory training is provided in a special department of the Chemical Laboratory. Practical instruction is given in the subjects of water, air, soils, antiseptics, and disinfectants, foods, diseases of animals transmissible to man. The diploma in Public Health may be obtained by any Bachelor of Medicine of the University on his passing the required examination not less than twelve months after he has taken the degree of M.B. Every candidate for a diploma in Public Health shall give sufficient evidence by certificates: that after obtaining the degree of M.B. he has undergone the practical training prescribed above, and that he has, after obtaining such degree, practically studied for six months the duties of out-door sanitary work under the Medical Officer of Health of a county or large urban district, or else has himself held an appointment as Medical Officer of Health under conditions not requiring the possession of a special sanitary diploma; and that he has attended the clinical practice of a hospital for infectious diseases recognised by the University, provided that such a course of instruction may not have been taken as part of the curriculum for his degree of M.B. The examination is written, practical, and oral. The fee for the course of instruction is £10 10*s.*, and for the examination £5 5*s.*

University of Aberdeen.—The diploma in Public Health (D.P.H.) is conferred only on graduates in Medicine of a University in the United Kingdom; and a period of not less than twelve months must elapse between medical graduation and entrance to the examination for the diploma. Every candidate must produce evidence of having attended, after graduation in Medicine, during a period of six months, practical instruction in Hygiene in a laboratory approved of by the University, together with having for a like period after graduation practically and daily studied the duties of out-door sanitary work under the Medical Officer of Health of a county or large urban district, or also of having himself held appointment as Medical Officer of Health. He must also have regularly attended for six months the wards of a general fever hospital containing not less than fifty beds. Every candidate who is not a graduate in Medicine of this University must have attended a course of instruction in the University in one or more of the subjects embraced in the examination for the diploma. The diploma is conferred after an examination in Public Health held in March and July of each year. Candidates desiring to appear for examination at either of these periods must send in their names, with the necessary fee, to the Secretary of the Medical Faculty before the first day of the month in which the examination takes place. The fee for the examination is £5 5*s.* The examination is conducted by specially qualified examiners appointed by the University. Candidates may enter for the whole examination at one period, or they may enter for Parts I. and II. at one period and for Parts III. and IV. at another and subsequent period.

The Royal Colleges of Physicians and Surgeons of Edinburgh and the Faculty of Physicians and Surgeons of Glasgow.—All candidates for the diploma in Public Health must have been qualified for at least one year. Those qualified before 1890 and also those who have held the position of Medical Officer of Health to a county or to an urban district of more than 20,000 inhabitants, or an entire rural sanitary district, do not require to produce evidence of attendance on any special courses. All other candidates must have attended, after qualifying, six months' practical instruction in a recognised public health laboratory, and must have studied for six months the duties of out-door sanitary work under the Medical Officer of Health of a county or large urban district, or must themselves have held an appointment as Medical Officer of Health under conditions not requiring the possession of a sanitary diploma. It is also recommended where possible to take out a course of instruction in the diseases of animals transmissible to man.

There are two examinations, and candidates may enter for both at one period or for either separately. The First Examination includes Chemistry, with laboratory work, physics, and meteorology; the Second Examination embraces epidemiology and endemiology, vital statistics, practical sanitation, and sanitary law, together with a practical examination and report on cases in a hospital for infectious diseases, of the sanitary condition of premises to be visited, and of carcases (diseased or otherwise) in a public abattoir. The fee is 10 guineas for both examinations, or 5 guineas for either of them. The examination is held twice yearly in May and October. The published regulations provide detailed synopses of the subjects of examination and give lists of books from which to select. The Registrar for Edinburgh is Mr. James Robertson, 1, George-square; and that for Glasgow Mr. Alexander Duncan, 242, St. Vincent-street.

IRELAND.

Royal University of Ireland.—This University grants a diploma in Sanitary Science. It is conferred only on graduates in Medicine of the University. Candidates are not admitted to this examination until the lapse of twelve months from the time of obtaining the first registrable qualification; they must give notice in writing to the Secretaries of their intention to present themselves and must pay the fee, £2, at least one month previously to the examination. Candidates are required to produce a certificate of having, after obtaining the degree of M.B., B.Ch., B.A.O., attended six months' practical instruction in a laboratory approved by the University, and also of having for six months practically studied the duties of out-door sanitary work under the Medical Officer of Health of a county or large urban district.

University of Dublin.—The diploma in State Medicine is conferred, after examination, on the following conditions:—The candidate must be a Doctor in Medicine, a graduate in Medicine and Surgery of Dublin, Oxford, or Cambridge. The name of the candidate must have been on the Medical Register at least twelve months before the examination. The candidate must have completed, subsequently to registration, six months' practical instruction in a laboratory approved by the University and also have studied practically out-door sanitary work for six months, under an approved officer of health. The subjects of examination will be—(*a*) State Medicine and Hygiene, including causation and prevention of disease, contagion in different diseases, morbid diathesis, congenital diseases and malformations, diseases of animals in relation to the health of man, diseases of the vegetable kingdom, famine diseases, causes of origin and spread of epidemics, principles of bacteriology, quarantine, disinfection &c.; (*b*) Chemistry, including air, water, and articles of food and drink, and their chemical and microscopical examination and analysis, the detection of common poisons and recognition of injurious pigments &c.; (*c*) Physics and Meteorology; (*d*) Engineering; (*e*) Morbid Anatomy; (*f*) Vital Statistics; (*g*) Medical Jurisprudence; (*h*) Practical Sanitary Engineering.

Royal College of Physicians and Royal College of Surgeons in Ireland.—Stated examinations for the diploma in State Medicine are held on the Tuesday, Wednesday, and Thursday following the first Friday of the months of February, May, and November. A special examination for the diploma can be obtained on payment of £5 5*s.*, in addition to the ordinary fees mentioned below, and on giving notice at least one fortnight before the date of the proposed examination. Every candidate for the diploma in State Medicine must be a registered medical practitioner. He must subsequently to qualification (1) receive six months' laboratory instruction in Chemistry, Bacteriology, and the Diseases of Animals transmisible to man, and (2) during six months either practically study out-door sanitary work under a Medical Officer of Health or himself hold an appointment of Medical Officer of Health under conditions not requiring the possession of a special sanitary diploma. Candidates beginning the study of sanitary science after Jan. 1st, 1894, shall be examined on four days commencing on the first Tuesday of February, May, and November, and shall as an additional requirement attend a hospital for infectious diseases. Each candidate must return his name to the secretary of the committee of management under the conjoint scheme three weeks before the examination, and lodge with him a testimonial of character from a Fellow of either of the Colleges, or of the Royal Colleges of Physicians or Surgeons of London or Edinburgh. The fee for the examination is £10 10*s.* The examination for the diploma in State Medicine comprises the following subjects:—State Medicine

Digitized by Google

and Hygiene, Chemistry, Meteorology and Climatology, Engineering, Morbid Anatomy, Vital Statistics, Medical Jurisprudence, Law. For further particulars apply to the Secretary, Committee of Management Office, Royal College of Physicians, Dublin.

DENTAL SURGERY.

ANYONE who is on the Medical Register is entitled to practise as a dentist, although he cannot register as such without the special licence; but it is of eminent advantage to take the L.D.S., otherwise few dental appointments at general or special hospitals or dispensaries are available, and, what is still more important, the manual dexterity and knowledge of mechanics requisite for the successful practice of dentistry can only be gained by long and careful training at the dental operating chair and in the dental laboratory; and, this having been attained, it costs but little trouble to pass the special examination. The subjects beyond those included in the general qualification are—Dental Anatomy and Physiology (Human and Comparative), two courses; Dental Surgery, two courses; Dental Mechanics, two courses; Metallurgy, one course; Practice of Dental Surgery at a recognised school, two years, and an apprenticeship in Dental Mechanics to a competent practitioner for three years, but in the case of qualified surgeons two will suffice. The Dental Schools in London are the Dental Hospital of London, the National Dental Hospital and College, and Guy's Hospital Dental School. Most of the large provincial towns have now dental hospitals. A convenient arrangement by which the M.R.C.S., L.R.C.P., and L.D.S. can be taken is as follows:—The Preliminary Examination in General Education having been passed, the student should become apprenticed to a qualified dentist and register as a dental and medical student. (This instruction, however, may be taken prior to the date of registration as a dental student.) During his apprenticeship the student should receive instruction in Chemistry, including Chemical Physics, Practical Chemistry, Pharmacy, and Materia Medica, and pass in these subjects before entering the hospital. Having entered the hospital, the student should attend the dental and general courses contemporaneously, and pass the Elementary Anatomy Examination at the end of the first winter session, and at the end of the second winter the Second Conjoint Examination in Anatomy and Physiology. When time permits it is advisable to attend the general hospital only until after the First and Second Conjoint Examinations have been passed. At this point a break may be made to admit of the completion of the dental curriculum and the passing of the final examination for the L.D.S. diploma. The best course, however, is to entirely finish the curriculum for the M.R.C.S. and L.R.C.P. and then take the special Dental work. The student should now devote the rest of his time to the requirements of the Conjoint Board. The regulations for the Dental Licence of the Royal Colleges of Ireland and Edinburgh and of the Faculty of Physicians and Surgeons of Glasgow are very similar to those of the English College. The L.D.S. can also be obtained alone.

REGISTRATION OF DENTAL STUDENTS.

The registration of dental students is carried on at the Medical Council Office in London in the same manner as the existing registration of medical students, and subject to the same regulations as regards Preliminary Examinations. Students who commenced their professional education by apprenticeship to dentists entitled to be registered, or by attendance upon professional lectures before July 22nd, 1878 (when dental education became compulsory), are not required to produce evidence of having passed a Preliminary Examination. Candidates for a diploma in Dental Surgery must produce certificates of having been engaged during four years in professional studies, and of having received three years' instruction in Mechanical Dentistry from a registered practitioner. One year's *bonâ-fide* apprenticeship with a registered dental practitioner, after being registered as a dental student, may be counted as of the four years of professional study. The three years of instruction in Mechanical Dentistry, or any part of them, may be taken by the dental student either before or after his registration as a student; but no year of such mechanical instruction will be counted as one of the four years of professional study unless taken after registration.

[redacted] for anyone practising Dental Surgery in [redacted], and no foreign qualifications are admitted. Formerly exception was made with regard to the Universities of Harvard and Michigan.

The Royal College of Surgeons of England grants a diploma in Dental Surgery under the following regulations: A candidate must produce certificates: 1. Of registration as a dental student by the General Medical Council, 299, Oxford-street, London, W. 2. Of having been engaged during four years in the acquirement of professional knowledge subsequently to the date of such registration. 3. Of having received instruction in Chemistry, including Chemical Physics, Practical Chemistry, and Materia Medica. 4. Of having attended a recognised medical school where he followed (*a*) a course of lectures on Anatomy during not less than six months, or one winter session; (*b*) a course of lectures on Physiology during not less than six months, or one winter session; (*c*) a separate practical course of Physiology during not less than three months; (*d*) a course of lectures on Surgery during not less than six months, or one winter session; (*e*) a course of lectures on Medicine during not less than six months, or one winter session. (Students are required to attend examinations, which are held in the several classes. 5. Of having performed dissections at a recognised school during not less than twelve months. 6. Of having attended at a recognised hospital or at hospitals in the United Kingdom the practice of Surgery and clinical lectures on Surgery during two winter sessions. 7. Of having attended at a recognised school two courses of lectures upon each of the following subjects: Dental Anatomy and Physiology (Human and Comparative), Dental Surgery, Dental Mechanics, and one course of lectures on Metallurgy, by lecturers recognised by this College. Students are required to attend examinations which are held in the several classes. 8. Of having been engaged during a period of not less than three years in acquiring a practical familiarity with the details of Mechanical Dentistry under the instruction of a competent practitioner. In the cases of qualified surgeons evidence of a period of not less than two instead of three years of such instruction will be sufficient. This instruction may be taken prior to the date of registration as a dental student. 9. Of having attended at a recognised dental hospital, or in the dental department of a recognised general hospital, practice of Dental Surgery during the period of two years. 10. Of being twenty-one years of age. (Professional study prior to the date of registration as a dental student is not recognised except in the case of Chemistry, Practical Chemistry, and Materia Medica, and of instruction in the details of Mechanical Dentistry—see Clauses 3 and 8.) Candidates who have passed the Second Examination of the Examining Board in England, or who shall produce evidence of having passed the Examination in Anatomy and Physiology required for the Licence in Surgery of the Royal College of Surgeons of Edinburgh, the Royal College of Surgeons of Ireland, or the Faculty of Physicians and Surgeons of Glasgow, or an Examination in Anatomy and Physiology required for a Degree in Medicine or Surgery at a University in the United Kingdom, will be exempted from re-examination in those subjects. Candidates who are Members of the College, or who have passed the examination in Surgery of the Examining Board in England, or who shall produce evidence of having passed the examination in Surgery for the Licence of the Royal College of Surgeons of Edinburgh, the Royal College of Surgeons in Ireland, or the Faculty of Physicians and Surgeons of Glasgow, or an examination in Surgery for a degree in Medicine or Surgery at a University in the United Kingdom, will be exempt from re-examination in Surgery and Pathology. A candidate whose qualifications are found insufficient will be referred back to his studies and will not be admitted to re-examination within the period of six months unless the Board shall otherwise direct. The fee for the diploma is £10 10s., not including stamp duty.

Royal College of Surgeons, Edinburgh. Incorporated For the licence in Dental Surgery all candidates must pass a preliminary examination in general knowledge and have their names inscribed in the Register of Dental Students of the General Medical Council. A copy of regulations and a list of preliminary examinations recognised for entering this licence, as well as of the subjects of the professional examinations, may be obtained from Mr. Robertson, Clerk to the Royal College of Surgeons, 1, George-square, Edinburgh. Students who have begun their professional education by apprenticeship or by attendance on lectures before July 22nd, 1878, are exempted from the preliminary examinations. Candidates must produce

Digitized by Google

of having, subsequently to the date of registration, been engaged for four years in professional studies, and of three years' instruction in Mechanical Dentistry from a registered dental practitioner, except in the case of previously registered medical practitioners, when two years will be considered sufficient. 1. Candidates who have commenced their studies *prior* to Oct. 1st, 1890, must have attended the following curriculum: Anatomy, one winter course; Practical Anatomy and Demonstrations, nine months, or Practical Anatomy, nine months, and Anatomy of Head and Neck, one course of twenty lectures; Physiology, one course of not less than fifty lectures; Chemistry, one winter course; Surgery, one winter course; Medicine, one winter course; Materia Medica, one course of three months; Practical Chemistry and Metallurgy, one course of three months; attendance on the practice of Surgery and Clinical Lectures on Surgery, at a recognised hospital, one course of six months, or two courses of three months. 2. Candidates commencing their studies *after* Oct. 1st, 1890, must have attended the following curriculum: Anatomy, one course of six months; Practical Anatomy, twelve months; Chemistry, one course of six months; Practical Chemistry, one course of three months; Physiology, one course of six months; Materia Medica, one course of three months; Surgery, one course of six months; Medicine, one course of six months; attendance on the practice of a recognised general hospital, with Clinical Instruction, twelve months. (Candidates who commenced study in accordance with the regulations in force before July, 1895, shall not be required to attend more than six months' hospital work.) These courses must have been attended at a University, or in an established school of medicine, or in a provincial school specially recognised by the College as qualifying for the diploma in Surgery. In addition to these courses candidates will be required to have attended in a recognised dental hospital, or with teachers recognised by the College, the following special courses of lectures and instruction: Dental Anatomy and Physiology (Human and Comparative), Dental Surgery and Pathology, Dental Mechanics—one course each; two years' attendance at a dental hospital or the dental department of a general hospital recognised by the College. Certificates of attendance on such of these courses of the new curriculum as may be respectively required will entitle candidates to appear either for the first dental examination or for the first and second examinations for the triple qualification as they may select, and subject to the existing regulations for each qualification. Candidates who have passed the first and second examinations for the triple qualification under the four years' course will be exempt from the first dental examination, and will have the advantage of being admissible either to the Final Dental Examination or to the Final Examination for the Triple Qualification, or to both. But the First Dental Examination will not be held as equivalent to the first and second Triple Examinations, and will admit to the Final Dental Examination only. Candidates who are Licentiates of this College, or who may be registered medical practitioners, will be required to produce certificates of attendance on the special subjects only, and will be examined in these only for the Dental diploma. First Professional Examination: The candidate must have attended the courses on Anatomy, Chemistry, and Physiology. The examination embraces Anatomy, Chemistry, and Physiology. The fee is £4 4s. Second Examination: The candidate must have attended the remaining courses of the curriculum, must be twenty-one years of age, and must pay a fee of £6 6s. The examination embraces Surgery, Medicine, Therapeutics, and the special subjects of Dental Anatomy and Physiology, Dental Surgery and Pathology, and Dental Mechanics. Unsuccessful candidates will be repaid £2 2s. in the First and £3 3s. in the Second Examinations. Candidates who claim exemption from the First Dental Examination, on the ground of having passed the First and Second Triple Qualification Examinations, will, before being admitted to the Second Dental Examination, be required to pay the total fee of £10 10s., payable for the Dental diploma, of which £3 3s. will be returned in case of rejection.

Faculty of Physicians and Surgeons of Glasgow.—The regulations as to certificates, curriculum, number, and subjects of examinations, fees &c., are in effect similar to those of the Royal College of Surgeons of Edinburgh. Special provision is made for candidates who intend to qualify both in Medicine and in Dentistry. There is a practical examination in Mechanical Dentistry and also an examination in Practical Dentistry conducted in a dental hospital.

Royal College of Surgeons in Ireland.—All information concerning the licence in Dentistry may be obtained from the Registrar of the College, who will receive the applications of candidates for permission to be examined. The bank receipt for fees, together with all certificates, &c., are to be lodged with him at least seven days prior to the day fixed for the commencement of the examination. The Primary Dental Examinations commence on the second Monday in the months of February, May, and November. The Final Dental Examinations commence on the Thursdays immediately following the Primary Dental Examinations. Candidates are required to pass three examinations—viz., Preliminary (in General Education), Primary Dental, and Final Dental. Preliminary Examination.—All examinations in general education recognised by the General Medical Council are accepted by the College. Preliminary Examinations are held conjointly by the Royal Colleges of Physicians and Surgeons on the third Wednesdays in March and September. Primary Dental Examination, £10 10s.; re-examination, if rejected, £5 5s. Every candidate[1] is required, before admission to the Primary Dental Examination, to produce evidence: (1) of having passed a recognised preliminary examination and of having been registered as a medical or dental student by the General Medical Council; (2) of having, subsequently to registration as a dental or medical student, attended at a recognised medical school the following courses: Lectures on Practical Anatomy, including Dental Anatomy, six months; Demonstrations and Dissections, two courses of six months each; Lectures on Chemistry, six months; Lectures on Physiology including Dental Physiology, six months; Practical Histology; Practical Chemistry, including Metallurgy, three months; (3) of having attended Clinical Instruction at a recognised general hospital for one year. The subjects of this examination are: (1) Physics;[2] (2) Chemistry, including Metallurgy; (3) Anatomy; (4) Physiology and Histology; and (5) Surgery. Final Examination.—Candidates holding L.R.C.S.I. or students who have passed Primary Dental or Third Professional Examination of the College, £10 10s.; re-examination, £5 5s. Fees for Final Examination of all other candidates, £26 5s.; re-examination, £10 10s. Extra fee for Special Examination, £5 5s. Candidates must produce evidence of having passed the Primary Dental Examination of this College, or the Third Professional Examination under the Conjoint Board with the Royal College of Physicians in Ireland, or with the Apothecaries' Hall, or an equivalent examination recognised by the College, and are required to produce certificates of having attended: (1) the following courses of lectures recognised by the College: Dental Surgery and Pathology (two courses), Dental Mechanics (two courses); (2) for two years the practice of a dental hospital recognised by the College, or of the dental department of a general hospital so recognised; (3) of having been engaged during four years in professional studies; (4) of having received three years' instruction in Mechanical Dentistry from a registered dentist. Candidates holding a diploma in Surgery shall be admissible to the Final Dental Examination on producing certificates of having attended: (1) One course of Lectures on Dental Surgery and Pathology; (2) One course of Lectures on Dental Mechanics; (3) For one year the practice of a Dental Hospital recognised by the College, or of the Dental Department of a General Hospital so recognised, where such attendance has been subsequent to the date of diploma (this remission (3) has been made on the understanding that the surgeon devotes his whole time to dental work); (4) of having been engaged during a period of not less than two years in acquiring a practical familiarity with the details of Mechanical Dentistry under the instruction of a registered dentist. The following are the subjects of examination: Dental Surgery, Theoretical (including Dental Pathology), Clinical, and Operative; Dental Mechanics, Theoretical, Clinical, and Practical (including the Metallurgy of the workshop). Examinations for the Licence in Dentistry *sine curriculo*: The Council has power to admit to examination, *sine curriculo*, candidates whose names are on the Dental Register, published under the direction of

[1] Candidates educated in England or Scotland are admitted to the Primary Dental Examination on the production of the certificates that would be necessary for both Primary and Final Examinations in their own countries.

[2] Candidates who have passed in Chemistry and Physics at a First Professional Examination under the Conjoint Board with the Royal College of Physicians in Ireland, or with the Apothecaries' Hall, or an equivalent examination, recognised by the College, are exempted from examination in these subjects at the Primary Dental Examination.

the General Medical Council, and who are unable to furnish the certificates required by the foregoing regulations, on presentation of a special schedule of application.

TEACHING INSTITUTIONS.

ENGLAND.

Dental Hospital of London and School of Dental Surgery, Leicester-square.—The school was founded to provide the special dental education required by the Royal College of Surgeons for the licence in Dental Surgery. The general part of the curriculum may be taken at any general hospital. The hospital is open from 9 A.M. to 4 P.M., there being one staff for the morning and another for the afternoon of each day. There is a good mechanical laboratory, under Mr. A. J. Watts, and opportunity is afforded students of gaining practical experience in taking models and fitting dentures into the mouth. The demonstrators at the commencement of each session give a course of lectures on Operative Dental Surgery. The five house surgeoncies are held for six months each, and are open to all qualified students. The lecturers, in addition to their lectures, give special demonstrations on the Microscopy of Dental Anatomy and Dental Surgery. The lecturer on Dental Mechanics also gives practical demonstrations in the mechanical laboratory. A scholarship of the value of £20 has been founded by Sir Edwin Saunders and will be awarded to the student who has obtained the highest aggregate number of marks in the five class examinations—viz., the four Lecturers' Prizes, the Operating Prize—and in additional special *viva-voce* examinations in Practical Dentistry. Prizes and certificates are awarded by the lecturers for the best examinations in the subjects of their respective courses, at the end of the summer and winter sessions. Arrangements have been made for a prize in Operative Dentistry. A prize of the value of 5 guineas is given by Messrs. Ash and Sons for the best essay on some surgical subject connected with Dental Surgery. The conditions under which this prize is to be competed for are the same as those for the Saunders Scholarship, with this exception, that the papers are to be written in the hospital during the summer session. Consulting Physician: Sir Richard Quain, Bart., F.R.S., M.D., F.R.C.P., LL.D. Consulting Surgeon: Mr. Christopher Heath, F.R.C.S. Consulting Dental Surgeons: Sir John Tomes, F.R.S., F.R.C.S., L.D.S., and Mr. T. Arnold Rogers, M.R.C.S., L.D.S. Dental Surgeons: Storer Bennett, L.R.C.P., F.R.C.S., L.D.S.; Mr. C. E. Truman, M.A. Cantab., M.R.C.S., L.D.S.; Leonard Matheson, L.D.S.; E. Lloyd Williams, L.R.C.P., M.R.C.S., L.D.S., L.S.A.; W. B. Paterson, F.R.C.S., L.D.S.; and W. H. Woodruff, L.D.S. Assistant Dental Surgeons: A. Clayton Woodhouse, M.R.C.S., L.D.S.; F. J. Bennett, M.R.C.S., L.D.S.; J. F. Colyer, L.R.C.P., M.R.C.S., L.D.S.; C. F. Rilot, M.R.C.S., L.D.S.; H. Baldwin, M.R.C.S., L.D.S.; H. Lloyd Williams, M.R.C.S., L.D.S.; W. H. Dolamore, L.R.C.P., M.R.C.S., L.D.S.; Percy Smith, L.R.C.P., M.R.C.S., L.D.S.; G. Hern, L.R.C.P., M.R.C.S., L.D.S.; J. G. Turner, L.R.C.P., F.R.C.S., L.D.S.; and A. R. Colyer, L.R.C.P., M.R.C.S., L.D.S. Anæsthetists: G. H. Bailey, M.R.C.S.; Dudley W. Buxton, M.D., B.S. Lond., M.R.C.P. Lond.; Frederic W. Hewitt, B.A., M.D. Cantab.; and Carter Braine, F.R.C.S. Assistant Anæsthetists: Henry Davis, M.R.C.S., L.S.A.; George Rowell, F.R.C.S.; E. A. Bridger, M.D.; and B. H. Comerford, M.R.C.S., L.R.C.P. Demonstrators: T. H. Clarence, L.D.S.; E. Gardner, L.D.S.; W. J. May, L.D.S.; and A. B. Densham, M.R.C.S., L.R.C.P., L.D.S. Medical Tutor: W. H. Dolamore, L.R.C.P., M.R.C.S., L.D.S. Curator of Mechanical Laboratory: A. J. Watts, L.D.S.I. Lecturers.—Dental Anatomy and Physiology (Human and Comparative): Arthur Underwood, M.R.C.S., L.D.S., on Wednesdays and Saturdays, at 8 A.M. (Summer). Dental Surgery and Pathology: Storer Bennett, L.R.C.P., F.R.C.S., L.D.S., on Tuesdays and Fridays, at 8 A.M. (Summer). Mechanical Dentistry: David Hepburn, L.D.S., on Wednesdays, at 5 P.M. (Winter). Metallurgy in its Application to Dental Purposes: Dr. Forster Morley, M.A., F.I.C., F.C.S., on Thursdays, at 5 P.M. (Winter). During the sessions the surgeons of the day will give demonstrations at stated hours. The house surgeons attend daily while the hospital is open. The Saunders' Scholarship of £20 per annum and prizes are open for competition. Fee for two years' hospital practice required by the curriculum, including lectures, £50 in one payment, or 50 guineas in two yearly instalments. The curriculum requires two years to be passed at a General Hospital; the fee for this is about £55. Both hospitals can be attended simultaneously. The Dean, Mr. Morton Smale, attends at the hospital every Wednesday morning from 10 to 12, and daily from 5 P.M. to 6 P.M. from Sept. 26th to Oct. 2nd, and from April 29th to May 28th, or he can be seen by appointment. Letters to be addressed—40, Leicester-square, "to be forwarded."

National Dental Hospital and College.—Winter Session, 1895-96, commences on Oct. 1st at the new building at the corner of Great Portland and Devonshire-streets, W.—Consulting Physicians: Sir B. W. Richardson and Sir W. H. Broadbent. Consulting Surgeons: Sir Spencer Wells and Mr. Christopher Heath. Consulting Dental Surgeon: Sir Edwin Saunders. Honorary Visiting Physician: Dr. James Maughan. Honorary Visiting Surgeon: Mr. E. W. Roughton. Dental Surgeons: Mr. F. H. Weiss, Mr. A. Smith, Mr. J. Davis, Mr. A. F. Canton, Mr. H. G. Read and Mr. C. V. Glassington. Assistant Dental Surgeons: Mr. W. Weiss, Mr. E. Beverley, Mr. S. W. Read, Mr. T. G. Read, Mr. Rushton, and Mr. W. H. Wheatley. Anæsthetists: Mr. C. Cosens, Dr. W. Reid Holmes, Mr. C. J. Ogle, Mr. G. Norton, Dr. J. Maughan, and Dr. Harold Low. Lectures (winter), Dental Anatomy and Physiology: Dr. J. Pare, Tuesdays and Thursdays, 5 P.M., in October, November, and December. Operative Dental Surgery: George Cunningham, Mondays, 6.30 P.M., in October, November, and December. Dental Materia Medica and Therapeutics: Mr. C. W. Glassington, Tuesdays, 7.30 P.M., in October, November, and December. Dental Metallurgy: Dr. W. Lapraik, Tuesdays, 7.30 P.M., in January, February, and March. Dental Mechanics: Mr. H. Rose, Mondays, 7 P.M., in January, February, and March. Summer—Dental Surgery and Pathology, Mondays and Thursdays, 6 P.M., in May, June, and July. Elements of Histology: Dr. J. Maughan, Mondays and Thursdays, 5 P.M., May, June, and July. The hospital is lighted throughout by electricity and warmed and ventilated by approved methods. Clinical Lectures and Demonstrations are given from time to time, and each student on entering passes through a preliminary course under a demonstrator. The stopping rooms have accommodation for sixty chairs. Dresserships in the extraction room are rearranged every three months. An Entrance Exhibition, of the value of £15, is open for competition at the commencement of each summer and winter session. Six prizes in medals are open for competition at the end of each course of lectures. Certificates of honour are awarded in each class. The Rymer Medal for General Proficiency, value £5, is awarded annually to the most meritorious student; and the Ash Prize, value £3 3s., for a thesis on a subject in Dental Surgery. General fee for the lectures required by the curriculum of the Royal College of Surgeons of England, £15 15s. For the Two Years' Hospital Practice required, £15 15s. Total fee for the Lectures and Hospital Practice required, £31 10s. Single Courses: Dental Anatomy and Physiology, Dental Pathology and Pathology, Operative Dental Surgery, and Dental Mechanics, each, one course, £2 12s. 6d.; two courses Dental Metallurgy, one course, £3 3s.; two courses Dental Materia Medica, £2 2s.; Demonstration of Dental Mechanics, Elements of Histology, each, £1 1s. Practice to registered practitioners by special permission of Committee, twelve months, £12 12s. Information regarding the Hospital Practice and the College may be obtained of the Dean, Mr. Sidney Spokes, who attends at the College, 40, Great Portland-street, on Tuesday mornings.

Guy's Hospital.—The work of the Dental Department begins daily at 9 A.M. both in the extraction room and in the conservation room. *The Extraction Rooms:* Patients are admitted between 9 and 10.30 A.M., and are seen by the dental surgeon for the day, the dental house surgeon, the assistant dental house surgeon, and the dresser. Such cases as are suitable for conservative treatment are transferred to the conservation room, taking with them a dental chart to indicate the treatment required. *Conservation Room:* This room is under the charge of the dental house surgeons from 9 A.M. till the completion of the extractions, and he receives patients as they come from the extraction rooms and allots the cases to the dressers. The members of the staff attend every morning, and on certain afternoons in the week to give demonstrations and otherwise assist students in their work in the Conservation Room and Mechanical Laboratory. Dental students have the opportunity of attending concurrently at the hospital the two courses of instruction required by the examining board for the L.D.S. Eng., viz., the lectures and practice of the Dental Department

Digitized by Google

general lectures and practice of the Medical School. The fees for these two courses may be paid separately, as shown in paragraphs (1) and (2) below, or together, as in (3), or they may be combined with the fees required to be paid for the course for a medical diploma, as in paragraph (4). (1) By a ticket which gives admission to the Special Lectures and Demonstrations and Dental Practice only on payment of £50 on entrance; (2) by a ticket which gives admission to the General Lectures, Demonstrations, and Hospital Practice required for the L.D.S.Eng. on payment of £60 paid on entrance, or 60 guineas paid in instalments of 30 guineas at the beginning of the first year and 30 guineas at the beginning of the second year; (3) a ticket which gives admission to the General and Special Lectures and Demonstrations, and to the Hospital and Dental Practice required for the L.D.S.Eng., may be obtained by payment of £110 on entrance, or of 60 guineas at the beginning of the first year and 50 guineas at the beginning of the second year. From these fees the reduction mentioned in No. 2 will be made; (4) the inclusive fee for students entering for the course of instruction for the M.R.C.S., L.R.C.P., and L.D.S. Eng. is 190 guineas paid in one sum, or 200 guineas paid by instalments at the commencement of each academical year. Students who pay this inclusive fee are allowed to pursue their study of Dentistry during any period of their medical course most convenient to themselves without further charge.

London Hospital.—Mr. Barrett gives practical instruction during the winter session on Tuesdays at 9 A.M., and during the summer session on Tuesdays and Thursdays at the same hour. The attention of dental students is particularly directed to the fact that the Council of the Royal College of Surgeons recognises the dental department of the London Hospital as a school at which may be obtained the dental practice necessary to qualify a student for the examination for the Dental diploma. Dental students may also obtain the general medical education (apart from certain lectures to be attended at the dental school) and the dental practice necessary for the diploma at the London Hospital School. In selecting from candidates for the office of Dental Assistant priority will be given to those who have attended the greatest number of lectures on Dental Pathology and Surgery, and have also been the most punctual in attendance in the dental department on the Tuesday mornings. During the summer a class for special instruction in filling teeth will be formed by Mr. Barrett.

Mason College, Birmingham.—The teaching of Dentistry is undertaken by the Mason College, acting in association with the Birmingham Dental Hospital and the Birmingham Clinical Board, so that the students may fully qualify themselves for the Dental diploma of the Royal Colleges. There is a special and well-equipped Dental Museum and Laboratory. Special courses of lectures are delivered on Medical and Surgical Diseases of the Mouth, &c., and there is a special course of Practical Dental Histology. An Entrance Exhibition, value £15, is awarded annually at the commencement of the winter session. Medals and honour certificates are awarded annually in the various classes.

Liverpool Dental Hospital, Mount Pleasant.—The Liverpool Dental Hospital, founded in the year 1864, combines the work of a most useful charity with all the advantages of a dental school recognised by all the licensing bodies of Great Britain and Ireland. During the past winter the whole of the top storey has been converted into one large operating room capable of accommodating fifty chairs. In its construction special attention has been paid to the ventilation and lighting; the electric light alone is employed for operating during the evening. Each chair has been provided with a specially constructed canting pendant which can be fixed at any angle. The chairs are of the well-known Morrison pattern, which, together with other fittings and fixtures, render this room one of the finest in the kingdom. There is an abundant daily supply of patients. Over 23,000 cases were treated during last year. The hospital staff consists of twelve honorary dental surgeons, one of whom is present each morning and evening. In addition to these there are one or more house surgeons to superintend all the hospital work and devote themselves to clinical teaching, advising and helping the students in their studies. Every facility is afforded to students who are anxious to acquire proficiency in Dental Surgery and to prepare themselves for the Dental diploma of the Royal College of Surgeons. The fee for the two years' Dental Hospital Practice required by the Royal College of Surgeons is £12 12*s.*, which must be paid on entrance. Fee as a perpetual student, £15 15*s.* Composition fee for all Lectures: a payment of £50 on entrance, or in two equal instalments (one-half on entrance and the remainder within twelve months). Fee for General Hospital Practice, £10 10*s.* All communications relating to the medical department should be addressed to Professor Paterson, Dean of the Medical Faculty, University College; and all communications relating to the Dental Hospital should be addressed to R. Edwards, 50, Mount Pleasant.

Bristol General Hospital.—Mr. Genge gives practical instruction in Dental Surgery at 9.30 A.M. on Mondays and Thursdays.

University College, Bristol.—Dental Students can enter for the full curriculum at Bristol. The Lectures are provided at the Medical School in connexion with this University. Practical instruction is given at the Royal Infirmary by Mr. Ackland and at the General Hospital by Mr. Genge, both institutions being recognised by the Dental Board of the Royal College of Surgeons. Full information may be obtained of the Dean of the Medical Faculty, Dr. A. B. Prowse, University College, Bristol.

Owens College, Manchester.—Arrangements have been made for dental students to attend the hospital practice at the Manchester Royal Infirmary and the practice at the Victoria Dental Hospital. Lectures on special subjects will be given in the College as follows:—Winter session: Dental Mechanics, Mr. Tanner, Thursday, 4 P.M. Summer session: Dental Anatomy and Physiology, Mr. Hooton, Tuesday at 4 P.M., Friday at 2 P.M. Dental Surgery, Mr. Campion, Tuesday and Friday, 3 P.M. Operative Dentistry, Mr. Whittaker, Wednesday: Lecture, 2.30 P.M.; Demonstration, 4 P.M. Dental Metallurgy, Dr. Burghardt, Monday, 2.30 P.M. Demonstrations in Dental Pathology and Histology, Mr. Headridge. For the course of Metallurgy the fee is £3 3*s.*; for other lectures, one course, £3 3*s.*; two courses, £4 4*s.* Dental practice for two years at the Manchester Royal Infirmary, £10 10*s.*; at the Victoria Dental Hospital at Manchester, £12 12*s.*, paid in advance, or £8 8*s.* for the first year and £5 5*s.* for the second year. At the Victoria Dental Hospital patients attend at 8.30 A.M. daily, and at 7 P.M. on Monday, Wednesday, and Friday. Consulting Physicians: Dr. H. Simpson and Professor D. J. Leech. Consulting Surgeons: Mr. E. Lund, Mr. F. A. Heath, Professor T. Jones, and Mr. J. Hardie. Consulting Dental Surgeons: Mr. H. Campion and Mr. G. W. Smith. Dental Surgeons: Mr. G. G. Campion, Mr. E. P. Collett, Mr. W. Dougan, Mr. L. Dreschfeld, Mr. J. W. Dunkerley, Mr. W. Dykes, Mr. W. Headridge, Mr. W. A. Hooton, Mr. I. Renshaw, Mr. W. Simms, Mr. W. Smithard, Mr. T. Tanner, and Mr. G. O. Whittaker. Assistant Dental Surgeons: Mr. P. A. Linnell, Mr. F. W. Minshall, Mr. C. R. Morley, and Mr. C. H. Smale. Administrators of Anæsthetics: Dr. A. Wilson and Dr. J. P. Stallard. Dean: Mr. G. G. Campion.

University College, Liverpool, School of Dental Surgery.—There is a school of Dental Surgery in connexion with the Medical Faculty. The curriculum includes Lectures and Demonstrations on all the subjects required for the licences in Dental Surgery of the Royal Colleges of England, Edinburgh, and Dublin, and of the Faculty of Physicians and Surgeons of Glasgow. In addition, Laboratory courses are conducted in Dental Histology and Dental Pathology. Practical instruction in Dentistry is given at the Dental Hospital in Mount Pleasant. Fees:—A payment of £50 on entrance, or in two equal instalments (one-half on entrance and the remainder within twelve months), entitles the student to attendance on all lectures and demonstrations (medical and dental) required for the Dental Diploma of the Royal College of Surgeons. The fee for two winter's hospital practice at the Royal Infirmary is £10 10*s.*, and for two years' dental hospital practice £12 12*s.* Further information can be obtained from the Dean of the Medical Faculty, Professor Paterson, University College, Liverpool.

Devon and Exeter Dental Hospital, Castle-street, Exeter.—Established 1880.—The hospital is open daily (Sundays excepted), and patients are admitted between the hours of 9 and 11 A.M. Students attending the practice of the hospital must consider themselves strictly under the control of the medical officers, and must not undertake any operation without the consent of the dental surgeon for the day. Hon. treasurer, Mr. J. M. Ackland; hon. secretary, Mr. Henry Yeo.

SCOTLAND.

The Incorporated Edinburgh Dental Hospital and School, 5, Laureston-lane, Edinburgh.—For the special classes, both theoretical and practical, required by dental students the

Digitized by Google

directors have secured the services of an efficient staff of dental officers and lecturers. There will also be a course of demonstrations in Mechanical Dentistry. Students will receive instruction in Practical Dental Mechanics under the mechanician. The fee for clinics in gold filling is included in the Dental Hospital fee of £15 15*s*. The minimum cost of classes for the whole course of dental instruction amounts to £78 13*s*. Consulting Physician: Dr. Alex. Peddie. Consulting Surgeon: Mr. Joseph Bell. Consulting Surgeon-Dentist; Dr. John Smith. Dental Surgeons: Messrs. W. Bowman Macleod, Andrew Wilson, Malcolm Macgregor, George W. Watson, J. S. Durward, James Mackintosh, and W. Forrester. Assistant Dental Surgeons: Messrs. John S. Amoore, J. Graham Munro, T. Gregory, John Turner, David Monroe, and F. Page. Extra Assistants: Messrs. Sewell Simmons, R. Nasmyth Hannah, Hume Purdie, Alexander Wilson, John Malcolm, and D. Baillie Wilson. Tutorial Dental Surgeon: Mr. Robert Lindsay. Dean: Mr. William Bowman Macleod, 16, George-square.

Dental Hospital and School, Glasgow. — The summer session was opened on Tuesday, May 7th, 1895, and the lectures are delivered as under:—Dental Surgery and Pathology, on Tuesdays and Thursdays, at 8 A.M. Mr. Rees Price, lecturer. Dental Anatomy and Physiology, on Tuesdays and Fridays, at 7 P.M. Dr. Wm. Wallace, M.A., M.B., L.D.S., lecturer. The winter session opens on Nov. 5th, 1895, and the lectures will be delivered as under: Dental Mechanics, on Tuesday evenings at 7 P.M., beginning Nov. 5th. Mr. John A. Biggs, lecturer. Fee for each of the above courses of lectures, £3 3*s*. The lectures on Dental Anatomy and Dental Surgery are arranged to extend over two summer sessions, as required by the English College, thus enabling students to present themselves for examination at any of the four Licensing Boards. The fees for attendance at the Dental Hospital and lectures amount in all to £25 4*s*., and can be paid separately, but may be compounded by a payment of £23 2*s*. on entering. Intending students before commencing to attend the lectures or hospital practice must produce evidence of having passed the preliminary examination prescribed by the regulations of the General Medical Council for registration of dental students. Dean: Mr. J. Rankin Brownlie. Secretary: D. M. Alexander, 97, West Regent-street, Glasgow. The hospital is open daily from 5 to 7 P.M. (Saturdays excepted); Saturdays from 9 to 11 A.M. Students may enrol at any time, their period of attendance counting from date of entry.

Glasgow Royal Infirmary (Dental Department).—Mr. W. H. Gray, L.D.S., attends at the Royal Infirmary at 3 P.M. on Mondays, Wednesdays, and Saturdays, and gives a course of Dental Surgery on these days in summer. The following course in the curriculum can be taken at St. Mungo's College: Anatomy, six months; Practical Anatomy, nine months; Physiology, six months; Chemistry, six months; Practical Chemistry with Metallurgy, three months; Surgery, six months; Medicine, six months; Materia Medica, three months; Clinical Surgery, six months; Dental Surgery, six months, and attendance for two years on the dental department of the hospital. The attendance on the Dental Clinic is free to students of the hospital; to dental students, one year, £5 5*s*.; perpetual, £10 10*s*.

CHANGES IN THE MEDICAL SCHOOLS AND HOSPITALS.

St. Bartholomew's Hospital.—At this hospital it has recently been decided by the Governors to elect an additional Physician and Assistant Physician. Dr. Lauder Brunton has been appointed Physician. During the past year Mr. Henry Power has resigned the office of Ophthalmic Surgeon, and Mr. Vernon has succeeded him. Mr. Jessop has been appointed Junior Ophthalmic Surgeon, Mr. H. J. Waring, M.S., F.R.C.S., has succeeded Mr. Jessop as Senior Demonstrator of Anatomy, and Mr. R. C. Bailey, M.S., has been appointed Demonstrator of Anatomy. Dr. Calvert has been succeeded as Assistant Demonstrator of Medicine by Dr. Fletcher. Dr. Horton Smith has been appointed Casualty Physician and Assistant Demonstrator of Physiology. Mr. A. N. Weir, Mr. P. Furnivall, and Mr. J. S. Sloane have been elected Assistant Demonstrators of Anatomy, and Mr. W. L. Brown and Mr. T. J. Horder have been appointed Assistant Demonstrators of Biology. Dr. Waldo, Medical Officer of Health for Southwark, has been appointed Tutor in Public Health.

Charing-cross Hospital.—Dr. Sangster has been appointed Consulting Physician for Diseases of the Skin, and Dr. Galloway has been appointed to succeed Dr. Sangster as Physician for ditto; Dr. Lubbock did not seek re-election at the annual meeting of governors as Physician in Charge of Out-patients; Dr. C. J. Arkle has been appointed Assistant Physician and succeeded as Curator and Pathologist by Dr. W. Hunter; Dr. Percy Smith has been appointed Lecturer on Psychological Medicine in place of Dr. Hack Tuke, deceased; Dr. H. P. Pollard has been appointed Lecturer on Biology to succeed Dr. Chalmers Mitchell, resigned; Dr. Patrick Manson has been appointed Lecturer on Diseases of Tropical Climates; Drs. Galloway and Arkle have been appointed Lecturers on Practical Medicine, to succeed Drs. Murray and Willcocks; and Mr. Collum has been appointed Surgical Tutor, to succeed Mr. Waterhouse; Dr. Mott, having been appointed Pathologist to the London County Asylums, a post just created by the London County Council, resigned his post as Lecturer on Physiology, and Dr. Pembrey, Demonstrator of Physiology, University of Oxford, has been appointed to succeed him.

St. George's Hospital.—Mr Rouse, Senior Surgeon, has been appointed Consulting Surgeon; Mr. Dent, Senior Assistant Surgeon; Mr. Herbert Allingham, Assistant Surgeon; and Mr. Grimsdale Assistant Ophthalmic Surgeon. Dr. Patrick Manson has been appointed Lecturer in Tropical Medicine: Dr. Alexander, Teacher of Clinical Lunacy; Dr. Ewart (late Lecturer in Practical Medicine), Lecturer in Advanced Practical Medicine; and Drs. Penrose and Dickinson, Lecturers in Practical Medicine. Mr. Cockle has been appointed Demonstrator in Chemistry.

Guy's Hospital.—Mr. Lane has been appointed Lecturer on Anatomy, and Mr. Dunn, Teacher of Operative Surgery in place of Mr. Jacobson and Mr. Symonds; Mr. F. Steward, M.B., B.S., has been appointed Demonstrator of Anatomy in place of Mr. Targett, who now holds the office of Demonstrator of Practical Surgery.

King's College Hospital.—Mr. Lyle takes the place of Mr. Brodie as Demonstrator in Physiology and Lecturer in Animal Biology. Mr. G. Stillingfleet Johnson, F.C.S., has resigned the Senior Demonstratorship of Chemistry.

London Hospital.—A second Lecturer on Physiology, Mr. Leonard Hill, has been appointed, who will take charge of the practical work and University of London Classes. A Second Lecturer (Mr. Hugh Candy) has been appointed in Chemistry. He lectures on Organic Chemistry and takes charge of the University of London Classes. Dr. F. J. Smith has succeeded Dr. Galloway as Demonstrator of Materia Medica. Mr. Arthur Keith has been appointed Senior Demonstrator of Anatomy in place of Mr. Hutchinson, Junior, and Dr. Schorstein has been appointed as one of the Pathologists in place of Dr. Charles Turner.

St. Mary's Hospital.—Mr. A. P. Laurie, M.A., B.Sc. has been appointed Lecturer on Chemistry in place of Dr. Wright (deceased); Dr. Sidney Phillips, Joint Lecturer on Medicine; Mr. H. B. Lacey, Demonstrator of Biology in place of Mr. F. A St. John (resigned); and Mr. Arthur Collier, F.R.C.S., Demonstrator of Anatomy, in place of Mr. W. Hill. Dr. W. Hill has been appointed Aural Surgeon Out-patients.

Middlesex Hospital.—During the year the following gentlemen have passed away: Dr. Goodfellow, Consulting Physician; Sir John Tomes, Consulting Dental Surgeon; Mr. J. W. Hulke, Senior Surgeon. Dr. J. J. Pringle, Consulting Physician, has resigned, but retains the office of Physician to the Department of Diseases of the Skin; Dr. A. E. Brown has been appointed Assistant Physician; Mr. Leopold Assistant Surgeon; Mr. W. McC. Wanklyn, Casualty Officer, vice Mr. W. A. Ward; Mr. Andrew Clark, Lecturer in Clinical Surgery; and Dr. J. J. Pringle, Lecturership in Practical Medicine. Mr. J. [illegible] been appointed Senior Demonstrator of Anatomy, Arnold Lawson and Mr. Reginald Gladstone, Demonstrators in Anatomy; Mr. L. Milburn, Demonstrator in Physiology and Biology; Mr. E. Protheroe Smith, Demonstrator in Physiology.

St. Thomas's Hospital.—Dr. T. Gregor Brodie has been appointed Lecturer in Physiology and Practical Physiology in the room of Dr. Sherrington; Mr. A. F. [illegible] has resigned the Demonstratorship of Physiology, and is succeeded by Dr. S. W. F. Richardson and Dr. [illegible]. Mr. Lawford has received the appointment of Senior Surgeon, Dr. A. W. Crossley Demonstrator of

Digitized by Google

Mr. H. R. Le Sueur Demonstrator of Physics and Assistant Demonstrator of Chemistry, Dr. Turney Demonstrator of Morbid Anatomy, and J. H. Fisher, M.B., B.S. Lond., F.R.C.S., Junior Demonstrator of Anatomy and Demonstrator of Ophthalmic Surgery. The following house appointments have just been made:—Resident House Physicians: E. G. C. Daniel, B.A. Cantab., and L. L. Jenner, M.A., M.B., B.Ch. Oxon. Non-resident House Physicians: P. J. A. Seccombe, M.A. Cantab., and F. G. Layton. House Surgeons: E. O. Thurston, A. L. Home, W. G. Stone, M.A., M.B., B.Ch. Oxon., and H. J. Davis, B.A., M.B., B.C. Cantab. Assistant House Surgeons: L. A. R. Wallace, B.A., M.B., B.Ch. Oxon., H. C. Crouch, J. L. Prain, and G. J. Conford, B.A., M.B., B.Ch. Oxon. Obstetric House Physicians — Senior: G. Candler, B.A. Cantab. Junior: E. A. Saunders, M.A., M.B., B.Ch. Oxon. Clinical Assistants in Special Departments—Throat: J. W. Cornwall, M.A., M.B., B.C. Cantab. Skin: G. G. Genge, and G. B. C. Blount. Ear: E. W. Palin, M.A., M.B., B.Ch. Oxon., and H. H. Haward, B.A. Cantab. Clinical Assistants in the Electrical Department: W. E. Dixon, B.Sc. Lond. Ophthalmic House Surgeon—Junior: A. H. P. Dawnay.

University College Hospital.—Dr. Bastian has resigned the Professorship of the Principles and Practice of Medicine, and Dr. Fred. T. Roberts has been appointed to succeed him. Dr. Roberts has resigned the Professorship of Materia Medica, and Dr. J. Rose Bradford, D.Sc., F.R.S., has been appointed as his successor. The title of the Chair now is "Materia Medica, Therapeutics and Pharmacology.

Westminster Hospital.—Soon after the beginning of the Winter Session the school suffered a great loss by the death of Dr. Sturges. He had been for twenty-seven years one of the chief teachers in the school and had but recently ceased to lecture on medicine. It has been decided to name one of the hospital wards after him, and a memorial is being raised by past and present members of the school in which some of the governors have joined. It is hoped that this will take the form of a prize or a scholarship in medicine. In consequence of the death of Dr. Sturges the following appointments have been made:—Dr. Potter, treasurer; Dr. De Havilland Hall, Physician to the Hospital; Dr. Gossage, Assistant Physician; Dr. J. P. Parkinson, Medical Registrar. Dr. Gossage has become Lecturer on Histology; Mr. A. H. Tubby has been appointed Assistant Surgeon and has been put in charge of the Orthopædic Department—he will give the Lectures on Minor Surgery and on Orthopædic Surgery; Mr. Brooksbank James has been appointed Assistant Demonstrator of Anatomy; and Mr. R. N. Watson, Demonstrator of Biology.

Mason College, Birmingham.—The chair of Midwifery, vacant by the death of Mr. John Clay, has been filled by the appointment of Mr. Edward Malins, M.D. Edin., M.R.C.P.; Mr. James W. Russell, M.A., M.D. Cantab., M.R.C.P., has been appointed Assistant to the chair of Medicine; Mr. J. T. J. Morrison, M.A., M.B., F.R.C.S. Eng., Assistant to the chair of Surgery; and Mr. C. E. Purslow, M.D., M.R.C.P., Assistant to the chair of Midwifery and Gynæcology. Mr. Wm. F. Haslam, F.R.C.S. Eng., has also been appointed Lecturer on Applied Anatomy.

Owens College.—Professor Ransome has resigned, and Dr. Paget alone takes charge of the class of Public Health. Mr. P. Thompson succeeds Dr. Chalmers as Demonstrator of Anatomy.

University College, Liverpool.—Physiology: Professor C. S. Sherrington, M.A., M.D., F.R.S., has succeeded Professor F. Gotch, M.A., F.R.S., appointed to Waynflete chair of in Physiology the University of Oxford. Dr. A. G. Gullan has been elected Demonstrator of Anatomy in place of Dr. Evans, resigned. Dr. R. J. M. Buchanan has been appointed Demonstrator of Toxicology, and Mr. J. A. Woods, L.D.S., Demonstrator of Dental Anatomy and Histology.

University College, Bristol.—Dr. J. E. Shaw has been appointed Joint Professor of Medicine in the place of Dr. Shingleton Smith, who has resigned; and Dr. Aust Lawrence has been appointed sole Professor of Midwifery, Dr. Swayne having resigned the half-chair.

Sheffield School of Medicine.—Dr. Harvey Littlejohn has been appointed Lecturer on Public Health vice Dr. Sinclair White; Dr. Andrew Walker, Assistant Demonstrator of Practical Physiology; and Dr. Wilkinson and Dr. Somerville Demonstrators of Practical Pathology.

Radcliffe Infirmary, Oxford.—Professor J. S. Burdon Sanderson, M.A., M.D., LL.D., F.R.S., has been appointed Consulting Physician, vice Sir H. W. Acland, Bart., K.C.B., M.D., resigned. W. Tyrrell Brooks, M.B. Lond., M.A. Oxon., W. Collier, M.A., M.D. Cantab., F.R.C.P. Lond., and G. J. Wilson, M.A. Oxon., M.D., M.R.C.S. Eng., are the Physicians, the last named gentleman being recently appointed. Alfred Winkfield, F.R.C.S. Eng., Horatio P. Symonds, M.R.C.S. Eng., F.R.C.S. Edin., and W. Lewis Morgan, M.A. Oxon., M.R.C.S., L.R.C.P. Lond., occupy the post of Surgeons. Ernest W. Blackburn, M.B., B.Ch. Oxon, M.R.C.S., L.R.C.P. Lond., has been recently appointed House Physician, as has also John Clay, M.B., B.S. Durh., House Surgeon. E. A. Bevers, M.R.C.S. Eng., L.S.A., is Consulting Dental Surgeon.

Anderson's College, Glasgow.—The following changes have taken place during the year:—Physics: Professor Peter Bennett, vice Professor Peter Alexander (deceased). Surgery: Professor T. Kennedy Dalziel, M.B., vice Professor James Dunlop, M.D. (resigned). Medical Jurisprudence: Professor R. M. Buchanan, M.B., vice Professor T. Kennedy Dalziel, M.B. (resigned). Hygiene and Public Health: Dr. J. Pearson Munro, vice Dr. W. Campbell Downs (resigned). Aural Surgery: Dr. James Erskine, M.A., vice Dr. Thomas Barr (resigned).

St. Mungo's College.—Dr. Lindsay Steven has resigned the chair of Pathology on being elected a Physician to the Royal Infirmary. Charles Workman, M.D., F.F.P.S.G., &c., has been appointed to the chair of Pathology. Alexander Thomson, M.A., LL.B. Advocate, has resigned the chairs of International Law, Public and Private. The vacancy has not been filled up.

University College, Dundee.—Chemistry: Professor James Walker, D.Sc. &c. Anatomy: Professor J. Yule Mackay, M.D. Medical Jurisprudence Lecturer: Dr Templeman. Mental Diseases Lecturer: Dr. Rorie. Ophthalmology Lecturer: Dr. McGillivray.

UNITED HOSPITAL ATHLETICS.

THE student, on entering at a London hospital, is early confronted with the question of athletic exercise, in what form it can be obtained, at the expense of how much time, and—a matter of great consequence to many students—at what cost. To obtain a satisfactory answer to this question—and it is one concerning which he will be unable to ascertain anything definite before his entry into the hospital—his best course of proceeding is, immediately on joining, to inquire for the secretaries of the various clubs, who will be only too glad to give every information in their power. The financial aspect of the question is settled in an excellent manner at some hospitals—e.g., Middlesex Hospital, by the addition to the total sum of fees paid by the student on joining of a sum of three, or at most five, guineas, which will make him a member of the amalgamated clubs, or of their various branches, for the whole five years of his curriculum. At other hospitals the system of payment by instalments—which may be compounded at any time by payment of a lump sum—is in vogue, and is of advantage to occasional students. With regard to the time expended on the pursuit of athletics, whilst they are necessarily of secondary importance to work, the student will find that his work does not suffer at all, but is even improved, by a certain amount of active exercise, even though he may grudge the time and discomfort involved in the railway journey which is unfortunately a necessary accompaniment to games played in the neighbourhood of London. On the other hand there is the acknowledged truism that he will be unable to work the whole of his time, and so, unless able to join with others in games of different kinds, he will find time fall very heavily upon his hands, and that socially he is apt to be relegated to a lower scale amongst his fellow students. There must unfortunately be always at a hospital some men who will rush to extremes in the matter of sport, and whose work consequently suffers; but as the student goes on he will notice—perhaps to his surprise—that many of the men who have done best in work at the hospital and in after-life have also been noted for prowess in the athletic field. With regard to the varieties of athletics open to the student there can be little cause of complaint. Several hospitals now possess private grounds, which are of inestimable value both by tending to improve the athletic status of the hospital and also socially by producing and maintaining friendly relations between senior and junior students.

Digitized by Google

Amongst those possessing private grounds are Guy's Hospital, at Honor Oak, and King's College, at Wormwood Scrubs. Within the past year St. Bartholomew's Hospital has followed their example by obtaining a ground within easy reach at Nunhead, whilst students at St. Thomas's Hospital have the benefit of practising upon the grounds adjoining Lambeth Palace. On these grounds cricket, tennis, and both varieties of football are played, whilst rowing and golf are practised by the students of some hospitals.

In RUGBY FOOTBALL St. Thomas's Hospital again succeeded in retaining the Cup, which they have held in succession for three years. Considerable excitement was caused by their drawing with St. Bartholomew's Hospital in the semi-final round, the score being one try each; but on their meeting a second time St. Thomas's Hospital won pretty easily and defeated Guy's Hospital in the final without much difficulty. A match was played with the United Hospitals of Dublin, in which the Londoners won by one try. In ASSOCIATION FOOTBALL Guy's Hospital and St. Bartholomew's Hospital contested the final, when the latter won by three goals to one after a hard game.

The CUP for LAWN TENNIS also fell to St. Thomas's Hospital, who defeated St. Bartholomew's Hospital by a narrow margin.

A BOXING CONTEST was held early in June last, but was unfortunate in the time and in the venue selected. It was only sparsely attended, and can hardly be considered to be representative. The majority of the events were won by University College Hospital.

A BICYCLING COMPETITION was held at Herne Hill, when Guy's Hospital and the London Hospital tied for first place. This is the first competition of the kind held under the auspices of the United Hospitals.

With regard to ATHLETIC SPORTS the Shield was won by Guy's Hospital by the narrow majority of half a point over St. Mary's Hospital, the scores being 3½ to 3. Munro again won the Mile and Three Miles, but Bell was beaten in the 100 Yards by Woodyatt, a fast sprinter from University College Hospital, and could only manage to make a dead-heat of the High Jump with Adams of Middlesex Hospital. Butler of St. Mary's Hospital won the Quarter- and Half-mile in very good time, establishing a hospital record for the latter distance. A contest took place with the Cambridge University Athletic Club, in which the hospital representatives, though beaten by 6 events to 3, made a very good fight, being only beaten by the very narrowest margins in two of the events. Altogether, it may be considered that the athletic sports are much the most satisfactorily managed branch of sport in connexion with the United Hospitals.

Guy's Hospital were again successful in retaining the HARE AND HOUNDS Cup for long distance running, and also obtained the Challenge Cup for WATER POLO by defeating St. Bartholomew's Hospital. The SHOOTING Cup, annually competed for at Bisley, fell again to St. Thomas's Hospital for the eighth year in succession.

OPENING OF THE MEDICAL SCHOOLS.

WINTER SESSION, 1895-96.

METROPOLITAN.

St. Bartholomew's Hospital.—The session will open on Tuesday, Oct. 1st. The old students' dinner will be held in the great hall of the hospital on the same evening.

Charing-cross Hospital.—The term will commence on Tuesday, Oct. 1st.

St. George's Hospital.—The school will open for the session on Tuesday, Oct. 1st, when the introductory address will be delivered by Mr. G. D. Pollock at 4 P.M.

Guy's Hospital.—The school begins its winter term on Tuesday, Oct. 1st. On the evening of the same day the first meeting of the Physical Society will be held, under the presidency of Dr. Wilks, F.R.S. Mr. George De'Ath will read a paper on Our Profession, our Patients, our Public, and our Press.

King's College Hospital.—Tuesday, Oct. 1st, is the date fixed for the opening of the Winter Session.

London Hospital.—The school opens on Tuesday, Oct. 1st. In the afternoon there will be a distribution of prizes to the students and probationers. On the same occasion the portrait of Dr. Hughlings Jackson, F.R.S., subscribed for by his friends on his retirement from the active staff of the Hospital upon the conclusion of his full term of office, will be presented to him. The old students' dinner will be held in the evening at 7.30 P.M. at the Criterion Hotel.

St. Mary's Hospital.—On the occasion of the opening, Tuesday, Oct. 1st, the Introductory Address will be delivered by Mr. A. P. Laurie, M.A., B.Sc. The annual dinner of past and present students will be held at the King's Hall, Holborn Restaurant, on the same evening Mr. Malcolm Morris in the chair.

Middlesex Hospital.—The session commences on Tuesday Oct. 1st. The introductory lecture will be given b Dr. W. Julius Mickle.

St. Thomas's Hospital.—The winter session will commence o Wednesday, Oct. 2nd, and terminate on March 31s The prizes will be distributed in the Governors' Ha on the same day at 3 P.M., when the introducto address will be delivered by Sir Edwin Arnol K.C.I.E., C.S.I. During the afternoon the vario departments of the hospital and school will be op for the inspection of visitors. Refreshments will provided in the Library. The annual dinner, in whi all former and present students are invited to join, w take place the same evening at the Hôtel Métropo at 6 for 6.30 o'clock, Dr. Payne in the chair.

University College.—The school opens on Tuesday, Oct. 1 and the introductory address will be delivered by J. Rose Bradford, M.D., D.Sc., F.R.S., at 4 P.M. annual dinner of the old and present students of Faculty of Medicine will be held at the Hôtel Mé pole on Tuesday, Oct. 1st, at 6.30 P.M. Profes Michael Foster, M.D., F.R.S., will preside.

Westminster Hospital.—The introductory address will delivered by Dr. Monkton Copeman, medical inspe H.M. Local Government Board. Lectures on Pu Health will be delivered on Tuesday, Oct. 1st, at 4 at the school, Caxton-street, and will be immedia followed by the distribution of prizes by the Right H Viscount Peel. The annual dinner will take plac the Café Monico at 7 P.M., Dr. de Havilland Ha the chair. Secretary of dinner, Dr. W. A. Wills.

School of Medicine for Women (Royal Free Hospit The winter session will begin on Tuesday, Oct when the opening address will be given by Ellaby, M.D., at 3.30 P.M.

Dental Hospital (Leicester-square).—The school ope Tuesday, Oct. 1st.

National Dental Hospital (Great Portland-street).—The ing date is Tuesday, Oct. 1st.

Pharmaceutical Society of Great Britain.—The fifty- session, 1895-1896, will commence on Wedn Oct. 2nd. The prizes of the last session will be buted by the President on Wednesday, Oct. 2nd P.M., and an inaugural address to the students given by Dr. Frederick T. Roberts, F.R.C.P., Pr of Medicine in University College, London.

Royal Veterinary College.—The opening address delivered by Professor Penberthy on Wed Oct. 2nd.

PROVINCIAL.

Mason College, Birmingham.—The term begins on T Oct. 1st, and the introductory address will b by Professor Percy F. Frankland, Ph.D., B.Sc., on Pasteur and His Work, the Debt of Med Chemistry.

Durham University.—The term will commence on Oct. 1st.

Yorkshire College, Leeds.—The opening address delivered by Prof. D. J. Leech, M.D., F.R Tuesday, Oct. 1st, and the prizes will be di on the same occasion.

Owens College, Manchester.—The term will comm Friday, Oct. 18th.

Digitized by Google

University College, Liverpool.—The College will open on Tuesday, Oct. 1st, at 3 P.M., when Mr. Jonathan Hutchinson, F.R.C.S., will deliver the Introductory Address. The foundation-stone will afterwards be laid of new Physiological and Pathological Laboratories.

University College, Bristol.—The winter session commences on Tuesday, Oct. 1st.

Sheffield School of Medicine.—Tuesday, Oct. 1st, is the date fixed for the opening of the winter term, and the introductory address will be delivered by Victor Horsley, F.R.S., at 4.30 P.M.

SCOTLAND.

Anderson's College, Glasgow.—Opens on Tuesday, Oct. 22nd.

St. Mungo's.—The session opens on Wednesday, Oct. 23rd, when Professor F. H. Napier, M.B., F.R.C.S., will deliver the inaugural address.

St. Andrews University.—The College formally opens on Tuesday, Oct. 8th, and the winter session will commence on the following day.

University College, Dundee.—The opening date of the term is Thursday, Oct. 10th.

IRELAND.

Queen's College, Cork.—The session commences on Tuesday, Oct. 15th.

Owing to the great pressure on our space we have been compelled to hold over till next week the List of Prizemen and Medallists at the Metropolitan Medical Schools.

Annotations.

"Ne quid nimis."

H.R.H. PRINCE EDWARD OF YORK.

IN an illustrated American paper of Aug. 17th a paragraph is published in which it is urged that a rumour which has circulated "all over the world" to the effect that Prince Edward of York is both deaf and dumb should, if untrue, be promptly contradicted as tending to give unnecessary pain to his parents and the rest of the Royal Family. We are glad to be able to state authoritatively that there is absolutely no truth in the report in question. Indeed, we have excellent reasons for knowing that Prince Edward of York is in every respect a very fine child, that he displays remarkable intelligence for his age, and that he can already repeat a number of words. Do our go-ahead American cousins expect a child nowadays to speak as soon as he (or she) is born?

THE ALLEGED DEARTH OF SKELETONS.

THE alleged dearth of skeletons is a matter of serious import to anatomical schools. A paragraph has lately been going the round of the American press from which it would appear that on the other side of the Atlantic a good skeleton commands the price of a good horse. Within three weeks of the issue of our Students' Number there will be an immense demand among students all over the United Kingdom for "bones," and it is gratifying to know that up to the present time there has been no paramount difficulty in meeting it. We hope that the price of "bones" will not go up with us, as we think that every student who can possibly afford it should have a set from which to study. The foundation of sound anatomy is a knowledge of the bones, and to acquire this a man must have a set always by him so that he can be constantly assuring and reassuring himself that the foundations are firm, even after he has reared upon them elaborate structures of after knowledge, physiological and embryological. Plates and diagrams are of every use, and good demonstrations are of invaluable assistance, but a deep familiarity with the "bones"—all the "bones" and all their minutest features, not a more or less temporary acquaintance with some of the salient points of the more recondite parts of the skeleton—is indispensable to the student of anatomy who desires to become an anatomist. Let every student who can possibly meet the necessary expense become the owner of a set. But to this word of advice we would add one word of caution. It is a good thing to study the "bones" used by another student occasionally, for sometimes a man will carry his acquaintance with one set of "bones" to such a point that he only knows the osseous points upon his private possession, and cannot distinguish, for instance, the borders and surfaces of the fibula upon a fellow student's unfamiliar specimen.

MEDICINE AND CRICKET.

IN days when something like a general conspiracy may seem to exist in the press to exalt athletic prowess unduly, some may, perhaps, question the wisdom of calling attention in our Students' Number to the cricketing feats of the medical profession witnessed during the season that is now closing. But the remarkable prominence of the position taken by several gentlemen following our calling demands, we think, a few words from us. The foremost cricketer the world has ever seen, who commenced the season of 1895 by surpassing in many ways all his previous performances, wonderful as they were and ranging over twenty-five years of first-class contests, Mr. W. G. Grace, is a medical man. His brother, Mr. E. M. Grace, who has but recently ceased to appear uniformly for Gloucestershire, is also a medical man. Other well-known names are those of Mr. Russell Bencraft, the careful and indefatigable captain of the Hampshire county team; Dr. W. J. Scott and Dr. G. Thornton, who each at different times rendered valuable service for Middlesex; Mr. J. A. Dixon, one of the few amateurs who played regularly for Nottinghamshire in the lace county's palmiest days, and who has struggled this year as hard as any member of the team to avert the fate that has befallen them of figuring so low upon the inter-county championship list; Mr. W. G. Heasman, a valuable though only occasional supporter of Sussex; and Dr. F. J. Poynton and Surgeon-Captain Trask, fairly regular members of the Somersetshire team. We do not attempt to make the list exhaustive, but only to give enough names to show that in the national game our profession has not been found wanting; and if the names are not many the form displayed is at any rate very high, while it must be remembered that it is not often that a medical man can find time to pursue a sport making such demand upon his time as first-class cricket. But when opportunity occasionally permits him to do so it is gratifying to find that his services are generally valuable to his side.

THE STORY OF THE HEALING ART.[1]

IT is a fact, acknowledged and regretted, that very few graduates and diplomates in medicine and surgery embark on professional practice with anything like an adequate appreciation of the history of their calling. Beyond some vague notions of the empiric, or more properly the "dæmonic," medicine of the East and of its first development as a science under Hippocrates, they know little or nothing of the steps by which the scientific stage was reached. How the Father of Medicine conceived and dealt with human maladies as a branch of natural history, to be studied like any other process of nature and mastered by observation, supplemented

[1] Medical History from the Earliest Times: a Popular History of the Healing Art. By Edward Theodore Withington, M.A., M.B. Oxon. With Two Illustrations. London: The Scientific Press, Limited. 1894.

Digitized by Google

by experiment and checked by experience; how the theorising tendency and the craving after "system" deflected the course of medical science and practice into channels issuing only in confusion and failure; how the reforms in method, inaugurated by Bacon and Galileo, gradually weaned the students and practitioners of the healing art from the seductions of "the high *priori* road," until the opening of the nineteenth century, and the progress made in physics, chemistry, and physiology—the so-called "institutes of medicine"—witnessed and promoted a return to the sound Hippocratic school,—all this, we say, is imperfectly known even in outline, still more imperfectly in detail, even by many consultants and teachers of the highest accomplishment in their respective walks. Medical history, as a branch of professional knowledge, indeed, has been too long a study by itself—a field exclusively cultivated by the curious in scientific scholarship and literature too long divorced from the appreciation of a calling which justly claims to be "liberal" in the same sense as theology and law. No student in divinity considers his equipment complete without a course of Church history; no student of law who aspires to the higher grades of the profession denies himself a survey, at the hands of a competent lecturer, of the successive phases through which the conception of right and its practical applications have passed. Medicine alone among the sister professions permits its votaries to leave its halls without that study of its past which "intelligent curiosity" alone would of itself seem to impose as at once a pleasure and a duty.

In proof of this we may notice the fact that until quite the other day the medical student—in the British Isles at least—had no work in the vernacular from which he might acquire a sound and comprehensive view of the rise and progress of his profession. France, Germany, Italy—all had histories of medicine, exhaustive or summarised, in which the student, whether thoroughgoing or superficial in his demands, could get what he wanted. Great Britain alone had nothing of either kind to show since Dr. Freind's treatise, published early in the last century, or the fragment by Dr. Meryon, which came to a premature stop in the later decades of the nineteenth. Int recen years, however, a growing sense of the importance of the subject, manifested even in the necessarily restricted articles on it in our encyclopædias, has elicited more than one treatise addressed to the British student. Translation, moreover, has brought within his range such admirable treatises as that of the Austrian Puschmann. And now, following closely on each other, we have had several abridgements, various in merit if identical in aim, of the master works of Harser, Puccinotti, and Daremberg, all of them appealing to the British practitioner and each of them supplying with more or less fulness and accuracy that survey of the medical past in which his interest has at length, if all too tardily, been awakened.

Of these works, by far the best is Dr. Withington's. He has come to his task well equipped with the necessary qualifications, professional, scholarly, and literary. His "standard" is high, quite in keeping with that of the University whose function was declared by one of its most eminent sons to be this: "To teach the student to know what knowledge of a subject means"; and he keeps throughout a watchful eye on what it is necessary his reader should be familiarised with and what he may without prejudice leave on one side. It is a history of medicine, in short, which the profounder student may accept as an introduction to the more exhaustive works of Continental, especially German, authors, and which the busy practitioner will find supplies him with all he may reasonably be expected to know. To have hit this happy mean has cost Dr. Withington no small pains, evidenced in the scrupulous care with which he dwells on the central figures of his subject, and relegates their satellites to compendious summaries, which he calls "Notes," for those who are content with nothing but the "omne scibile" of the subject. These notes consist largely of references to original and more voluminous authorities, and if followed up will place the reader in full enjoyment of the "atmosphere," so to speak—the environment, moral and material—in which the medical world of the special period lived and moved. A few test passages will assure the reader at once as to how far Dr. Withington has kept himself abreast of contemporary advance. Take, for instance, that devoted to Glisson, whose rehabilitation made peculiarly memorable Professor Virchow's recent visit to London. The reader will find that as regards the priority claimed for Haller in the discovery of "irritability," Gli anticipation of the great Swiss physiologist is establ beyond cavil. Again, the interesting section (pp. 254 on Paracelsus is quite up to date, the well-known vie Hirsch and Virchow on "that most striking figure amor physicians of the sixteenth century, perhaps in the of medical history," being evidently familiar to our a The appendices, too, on subsidiary points of m interest are well worthy of independent perusal; a them that on Mediæval Monastic Medicine, and, more, that on "the Galenic system" being careful judicious expositions of two much disputed episodes i history of medicine. But we have said enough to attra reader to a work as interesting as it is attractive, an merely add that the illustrations form a highly eff feature of some of its obscurer passages, and th elaborate, though not too minutely detailed, index faci references admirably.

THE SERVICES.

ANY man who has still to study with a view to pass examination is a student, and we take the opport therefore, in our Students' Number of printing the set in the last examination of candidates for entry Majesty's Army and Indian Medical Services. We a quently asked for copies of these examination papers an expression of opinion on the text. The questi natural science have been omitted.

Three hours allowed for each subject.

MEDICINE (DR. ALLCHIN).

1. Comment on the following cases in reference (A) nature and situation of the lesion, setting forth the g for the diagnosis; (B) the prognosis:—

A.

W. M——, fifty-two, a painter, admitted into hospital June 1 His family history unimportant. He has always been very ten Has never had syphilis. Is said to have suffered from acute n ten years ago, and two years since fell from a scaffold, breaki arms and cutting his forehead; the scar of the latter persists, right elbow has always been somewhat stiff since the accide months ago he is reported as having had a "fainting fit," particulars of it are to be obtained.

The present illness began on June 1st, when he was at work suddenly feeling giddy and almost falling, but with no loss of co ness. With assistance he was able to walk a short distance, three-quarters of an hour after the first attack whilst at home felt "queer" and giddy, and quickly lost power on his right s without any impairment of consciousness. He was at once take hospital and admitted.

On admission he was found to be well nourished, fully int completely paralysed in the right arm and leg, and with son facial paralysis. Speech thick, but no confusion of words. L rather larger than right; both act readily to light and accomm Movements of eyeballs normal. Tongue protruded to th General sensation in right arm and leg somewhat impaired. Ki equal and fairly sharp. Pulse 60, regular, full; vessels hard, impulse very indistinct, but felt slightly external to nipp accentuation of aortic second sound. A hyper-resonant percuss over the whole of the front of the chest. Nothing abnormal in the abdomen. No blue line at edges of gums. Urine, sp. acid, contains a trace of albumen, no sugar.

In the course of eight or nine days patient began to recov power in his shoulder and elbow, but was unable to move hi three weeks after the attack, by which time he could move tolerably well. He complained of occasional twitchings and tary startings of his right arm and cramp in his legs, but ther rigidity in either limb. Sensibility was completely restored. sign of facial paralysis was to be recognised on June 20th. T always contained a trace of albumin.

B.

J. P——, aged fifty, occupied all his life as a painter, admi hospital May 22nd, 1895. Nothing of interest or bearing on was ascertained in respect to his family history. He had b free from illness all his life, and could only remember "a slight colic" in 1871, and "rheumatism" in 1884, but no certain fa these ailments were obtainable. He had never had syph described himself as being "very temperate," which appears been true.

The illness for which he came under treatment began sud the early evening of Saturday, Jan. 19th, this year. He is have had a hearty dinner midday and also later a heavy tea half an hour after the latter, immediately following an actio bowels, he expressed himself as "feeling queer," and in two fell insensible across a table, though without injuring hims three weeks he remained unconscious, often very noisy, his s thick as to be unintelligible, frequently trying to get out of for the first week incontinence of urine and faces. From the right side of his face and right limbs were paralysed, the la pletely so. At the end of three weeks an improvement set i in his speech and his intelligence, and slowly continued, but t

Digitized by Google

very slight recovery of muscular power, and it was only with much difficulty and assistance that he could drag about.

On admission he appeared to be a well-nourished man, perfectly clear-headed and intelligent, with no noticeable defect of speech. Face slightly flatter on right side and drawn very little to the left, tongue protruded in straight line and lying evenly in the mouth, no ocular paralysis, pupils equal and react equally and well to light and accommodation. The power of voluntary movement in his right arm is limited to partial movement of his fingers, but he can raise the whole leg a short distance off the bed, and there is imperfect movement in the toes and at the ankle and knee. Sensation over the right arm is impaired, and he does not distinguish satisfactorily between heat and cold over the same limb; these defects are much less noticeable in the leg. The skin of both right limbs is much moister than on left side. The patellar tendon reflex is increased on both sides, but more marked on the right, and there is also ankle clonus on the same side. The plantar reflexes are very active, and the cremasteric reflexes noticeably sluggish.

Pulse 64, regular, small; arteries hard. Cardiac impulse displaced outwards and somewhat heaving in quality; first sound dull and prolonged, and aortic second sound accentuated. Lungs normal. No blue line on gums. Alimentary organs normal. Urine acid, pale, sp. gr. 1020, trace of albumen, no sugar.

During the next month patient remained in much the same state, the power in the right leg was sometimes rather better, and then appeared as if there were no improvement. Generally some stiffness was perceptible in the right arm, which occasionally was considerable. The urine continued as described.

2. Describe the morbid condition known as "fibroid phthisis," and the signs and symptoms upon which its diagnosis would be made.

3. What are the causes of chronic peritonitis? Describe the symptoms, course, post-mortem appearances, and treatment of a well-marked case.

4. Describe in full detail the entire treatment you would adopt for a severe case of scarlet fever complicated by acute nephritis in a young adult.

SURGERY (SIR WILLIAM MACCORMAC).

1. Enumerate the causes which may produce epididymitis. Give the symptoms, differential diagnosis, possible complications, and treatment succinctly of each form.

2. State in detail the circumstances which may render excision of the eyeball necessary, and describe the operation.

3. What causes tend to produce popliteal aneurysm in a young adult? Describe the changes which take place in the artery and adjacent structures, the treatment you would adopt, and the results which may follow.

4. Describe a case of severe cut-throat occurring in the more common situation. What structures may be involved or endangered? What complications may ensue? Give your treatment of the case.

CHEMISTRY AND MATERIA MEDICA (DR. SHORE).

1. Give an account of fluorine—how it has been isolated, its properties, and its most important compounds.

2. What is the chemical constitution of a fat? Into what substances is a fat resolved by heating it with steam under high pressure? What is the relation between a fat and a soap? Give equations.

3. Mention the chief remedies which may influence the heart's beat, and classify them according to their modes of action.

4. What is the botanical nature of ergot? Mention its preparations. Describe its physiological actions and its uses in medicine.

5. What is meant by "antagonism" between two drugs? To what extent are opium and belladonna antagonistic, and in what way are nux vomica and Calabar bean antagonistic to each other?

ANATOMY AND PHYSIOLOGY (MR. MAKINS).

1. Describe the cavernous sinus, mention its communications, and give its relations to included and surrounding structures.

2. Give the origin, course, relations, and distribution of the anterior crural nerve.

3. Describe the condition known as hemiopia. What varieties are met with, and how may they be explained on physiological grounds?

4. Give a short account of the manner in which the organic elements of food are prepared for absorption into the system, and state how the proteid, carbohydrate, and fatty elements respectively are taken up.

MR. WILLIAM C. ELLIS, L.R.C.P. and S. Edin., has received the award for efficient vaccination in the Tollerton district of the Easingwold Union.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.

ALLDEN, SIDNEY J., M.D., has been appointed Medical Officer of the Third District, Bridport Union.

HALL, GILBERT C., M.R.C.S. Eng., L.S.A. Lond., has been appointed Medical Officer of Health, Ambersley District, Droitwich Union.

HOGARTH, R. G., who has been appointed Senior Resident Medical Officer to the General Hospital, Nottingham, has recently been made a Fellow of the Royal College of Surgeons of England.

YEARSLEY, P. MACLEOD, F.R.C.S., has been appointed Clinical Assistant to the Central London Throat and Ear Hospital.

YOUNG, A. G., M.B., B.S. Dubl., has been appointed Medical Officer of the Billington District, Norton (out relief) Union.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

ASTON UNION.—Resident Assistant Medical Officer. Salary £100 per annum, with furnished apartments, rations, washing, &c.

CHESTERFIELD AND NORTH DERBYSHIRE HOSPITAL AND DISPENSARY.—House Surgeon, tenable for two years. Salary £100 per annum.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, Victoria-park, E.—House Physician for six months. Board and residence, and allowance for washing provided.

COUNTY COUNCIL OF CUMBERLAND.—Lady Lecturer in Nursing and Hygiene, qualified. Salary £100 and travelling expenses.

DENTAL HOSPITAL OF LONDON.—Two Demonstrators. The honorarium is £50 per annum.

DERBYSHIRE ROYAL INFIRMARY, Derby.—Clinical Assistant for six months.

GENERAL HOSPITAL, Nottingham.—House Physician for two years. Salary £100, rising £10 a year to £120.

GREAT YARMOUTH HOSPITAL.—House Surgeon on Oct. 3rd next. Salary £90 per annum, with board and lodging.

LANCASTER INFIRMARY AND DISPENSARY.—House Surgeon (unmarried). Salary £80, with residence, board, attendance, and washing.

METROPOLITAN HOSPITAL, Kingsland-road, N.E.—House Physician, House Surgeon, Assistant House Physician, and Assistant House Surgeon. Appointments for six months. The House Physician and House Surgeon will each receive a salary at the rate of £60 a year.

ROTHERHAM HOSPITAL AND DISPENSARY.—Assistant House Surgeon. No salary, but board, lodging, and washing provided.

ROYAL UNITED HOSPITAL, Bath.—House Surgeon for one year. Salary £60, with board, lodging, and washing.

ST. BARTHOLOMEW'S HOSPITAL AND COLLEGE.—Assistant Demonstrator of Chemistry.

ST. LEONARD, Shoreditch.—Resident Assistant Medical Officer. Salary £120 per annum, rising £10 annually to £150 per annum, with rations, furnished apartments, and washing in the Infirmary.

WARNEFORD ASYLUM, Oxford.—Locum Tenens for Assistant Medical Officer for four weeks.

WEST KENT SANITARY DISTRICT.—Medical Officer of Health. Salary £600 per annum and £100 for a clerk.

Births, Marriages, and Deaths.

BIRTHS.

KENNEDY.—On Aug. 28th, at 113, Balaam street, Plaistow, E., the wife of Angus E. Kennedy, L.R.C.P. Lond., M.R.C.S. Eng., L.S.A. Lond., of a daughter.

POPE.—On Aug. 31st, at Goldhawk-road, W., the wife of H. Campbell Pope, M.D. Lond., F.R.C.S., of a daughter.

MARRIAGES.

BANKS—DAVEY.—On Aug. 29th, at Holy Trinity, Ryde, Alfred Banks, F.R.C.S., to Elizabeth Maud, daughter of Alexander G. Davey, M.D.

SMITH—WILKS.—On Aug. 28th, at St. Mary's, Oatlands, T. W. Smith, M.D., to Alice Maud, daughter of the late J. J. Wilks.

DEATHS.

ALDRIDGE.—On Aug. 27th, in London, suddenly, Arthur Russell Aldridge, M.D., J.P., of Yeovil, Somerset.

CARTER.—On Aug. 30th, at Cambridge, James Carter, F.R.C.S.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

OUR CURRENT NUMBER

Being almost exclusively devoted to information especially interesting to Students, we are necessarily compelled to defer the publication of communications on other important subjects.

We tender our best thanks to those gentlemen who have kindly at considerable personal trouble supplied us with the returns and prospectuses upon which the information given in this Students' Number of THE LANCET *relative to the various medical examining bodies, hospitals, and medical schools of the United Kingdom is based.*

Communications, Letters &c. have been received from—

A.—Dr. J. Attlee, Lond.; Mr. H. E. Armstrong, Newcastle-on-Tyne; Messrs. Allen and Hanburys, Lond.; Alpha, Lond.

B.—Dr. P. H. Boyden, Bombooke Dock; Dr. D. C. Black, Glasgow; Dr. A. O. Bobardt, Barrier Reef, Queensland; Mr. F. Brown, Lond.; Mr. R. F. Bate, Sheerness; Mr. C. Birchall, Liverpool; Mr. M. G. Biggs, Lond.; Mr. J. Beckton, Lond.; Messrs. Blackie and Son, Lond.; Messrs. Burgoyne, Burbidges, and Co., Lond.; Birkbeck Literary and Scientific Institution, Lond.

C.—Dr. T. J. Croke, Harrogate; Dr. J. Culross, Newton Abbot; Mr. T. Cooke, Lond.; Mr. J. N. Cregeen, Liverpool; Mr. W. F. Clay, Edinburgh; Messrs. C. S. Cox and Co., Lond.; Messrs. C. J. Clay and Sons, Lond.; Cortland Wagon Co., Lond.; Chesterfield Hospital, Secretary of; Cumberland County Council, Carlisle, Secretary of; Class Rooms, Edinburgh; C. J. H., Lond.

D.—Dr. R. Drew, Hamburg; Surg.-Capt. H. E. Drake-Brockman, Bombay; Mr. A. Duke, Cheltenham; Mr. W. Duncan, Jersey; W. E. Davies, Rochdale; Mr. C. M. Davidson, Lond.

E.—Mr. W. C. Ellis, Yorkshire.

F.—Mr. H. J. Finch, Guildford; Mr. T. B. Flint, Manchester; Messrs. Fannin and Co., Dublin; Forceps, Lond.

G.—Mr. J. Gay, Lond; Messrs. Godfrey and Cooke, Lond.; Globe Advertising Co., Lond.

H.—Dr. W. S. Hedley, Brighton; Mr. M. P. Holt, Aldershot Camp; Mr. R. B. Hunt, West Ham; Mr. W. Herbert, Rickmansworth; Mr. G. Hermanni, jun., Lond.; Mr. G. Hamilton, Lond.; Mr. J. Heywood, Manchester; Mr. F. Hobday, Lond.; Mr. G. R. Harcourt, Lond.; Mrs. Heberden, Weston-super-Mare; L. N. Harding, Brighton; Messrs. Hooper and Batty, Lond.; Messrs. Hertz and Collingwood, Lond.; Messrs. Haasenstein and Vogler, Geneva; Hamilton Association, Lond.

I.—Mr. J. Iredale, Mablethorpe; Insurance, Nuneaton.

J.—Dr. C. E. Jennings, Lond.; Dr. Jangery, Dieppe; Mr. A. W. L. Jones, Aylesbury; Mr. Y. M. Jones-Humphreys, Cemmaes; Mr. T. Johnston, Wood Setton.

K.—Dr. C. F. Knight, Portobello; Mr. M. N. Korde, Umaria, India; Miss M. H. Kelly, Paris.

L.—Mr. H. K. Lewis, Lond.; Local London Press Exchange; Life Saving Society, Lond., Secretary of; Government Health Branch, Cape Town; Laryngo, Lond.

M.—Mr. A. B. Myers, Instow; Mr. T. C. Maguire, Lond.; Mr. H. M. N. Milton, Cairo; Mr. R. H. Monks, Wigan; Mr. R. G. Mullen, Bromley; Mr. F. G. Melkardo, Lond.; Messrs. Macmillan and Co., Lond.; M., Hythe; Medicus.

A Lecture
ON
THE TREATMENT OF ADENOID GROWTHS IN THE NASO-PHARYNX.

Delivered to Students attending the Course on Diseases of the Ear at Glasgow University, June 7th, 1895,

BY THOMAS BARR, M.D. GLASG.,

LECTURER ON DISEASES OF THE EAR, GLASGOW UNIVERSITY; AURAL SURGEON TO GLASGOW WESTERN INFIRMARY AND GLASGOW EAR HOSPITAL; AND AURIST TO GLASGOW SICK CHILDREN'S HOSPITAL.

GENTLEMEN,—We have already considered the symptoms of post-nasal growths, the defective nose breathing, the open mouth, the compressed nostrils, the snoring and even embarrassed breathing during sleep, the sluggish intellectual powers, and notably the defective hearing from middle-ear disease. Such a combination of symptoms occurring in early life generally denotes the existence of these growths in the naso-pharynx.

Importance of early removal.—We found that these vegetations tended to atrophy and disappear spontaneously when adult age is reached, and hence the question might be asked, Why not wait for their spontaneous disappearance? No doubt in slight cases, presenting few symptoms, and especially if unattended by ear mischief, no harm would follow the policy of waiting for their spontaneous disappearance. In most instances, however, such delay might be fraught with most important consequences. Dr. Semon gives the following pregnant reasons against delay in removing these growths: (1) the influence of the obstruction upon general health, mental development, and upon the formation of the face, results which remain for ever even if the glands themselves undergo atrophy; (2) the ever-present danger of ear complications; and (3) the greater liability to and seriousness of infectious diseases of childhood, especially diphtheria and scarlet fever, so long as the hypertrophic glands are present.

Modes of operating.—The operative is the only form of treatment worthy of consideration. Of the many methods of operating for the removal of these growths that with Gottstein's curette or some of its modifications is, I think, the simplest and most efficient. It is right, however, that you should be acquainted with the various other methods which are employed, and I shall describe these, as well as the operation with Gottstein's curette, in the following order: (1) the natural finger-nail; (2) the artificial nail; (3) Hartmann's curette; (4) Gottstein's curette or its modifications; (5) Golding-Bird's curette; (6) Lowenberg's forceps and modifications; and (7) Meyer's ring-knife. Sometimes a combination of methods is adopted—the forceps for removing the large tough portions, and the curette and finger-nail for the softer variety and for those growing on the lateral walls of the pharynx. We shall first, however, consider—

The question of anæsthetics.—The question of whether or not an anæsthetic should be administered in the removal of adenoid vegetations, and, if administered, which is the safest and best, has been much discussed.[1] There is no doubt that a general anæsthetic adds a slight element of risk to this operation, which, without an anæsthetic, may be said to be absolutely free from danger. On the other hand, it is found that in the cases of children or very nervous adults it is very difficult without an anæsthetic to eradicate the whole of the growths, at any rate at one sitting. A general anæsthetic is more frequently given in this country than on the Continent, where it is quite customary to repeat the operation, it may be, several times. One of the chief risks in operating under an anæsthetic is that of blood finding its way into the larynx or bronchial tubes, causing asphyxia or failure of the heart's action or subsequent inflammation of the lungs. This danger may be said to be almost entirely averted by the adoption of a suitable position for the patient, by the prompt use of sponges, and, above all, by a proper method of giving the anæsthetic. In regard to the position of the patient during anæsthesia most surgeons operate with the patient's head hanging backwards over the end of the operating-table, so that the blood or fragments of detached growth may pass out through the anterior nares or mouth. Unfortunately, this dependent position of the head tends for the time being to increase the bleeding, which, however, as a rule, soon ceases after the head has been raised. Some operators, such as Mr. Hovell, prefer that the head should be on a level with the body and trust to the rapid mopping up of the blood with sponges. Mr. Butlin operates with the patient on his side, the thighs being flexed and the head bent a little forward on a low pillow. Mr. Braine, in giving nitrous oxide gas and ether, chiefly for the operation with the finger-nail, first places the patient in the semi-recumbent position, and, when the narcosis is sufficiently complete, he flexes the trunk forcibly on the thighs—the blood escaping from the mouth and nose into a basin placed between the patient's knees. In the curette operation under an anæsthetic I always operate with the dependent position of the patient's head, and even then rapid removal of the blood by sponges is necessary to prevent the suction of blood into the trachea. With nitrous oxide gas the sitting posture may be justifiable. In regard to the kind of anæsthetic employed, the fact of several deaths having occurred from the use of chloroform has led some to discard it and to resort to ether or nitrous oxide gas, or to both. It is alleged in favour of ether that the power of coughing and swallowing is generally retained, and that the noisy respiration of ether anæsthesia, compared with the quiet breathing of chloroform, keeps you better informed as to the state of the respiration; while in the event of obstruction to the respiration the heart's action under ether does not fail so quickly. On the other hand, the large quantity of frothy secretion which is usually poured into the throat and the more profuse bleeding due to great venous turgidity are highly objectionable features of ether narcosis; while the laboured and stertorous breathing, instead of being an advantage, may rather tend to suck the blood and frothy secretion into the larynx. Nitrous oxide gas may suffice with the nail operation or even with a rapid curette operation, but it does not allow of sufficient time for the use of forceps. In order to save time the gag should be introduced before the beginning of the administration of the gas. Some operators begin with nitrous oxide gas, then go on to ether, and when the patient is fairly deeply anæsthetised they continue with chloroform till the end of the operation. While I have operated both with ether and nitrous oxide gas as anæsthetics, my experience has led me to prefer chloroform, cautiously and sparingly given on a mask, with a plentiful supply of air, care being taken that while the corneal reflex is abolished the cough and swallowing reflex should not be entirely in abeyance. It is important, however, that, though very deep chloroform narcosis is to be avoided, it should be deep enough to relax the muscles of the face and to prevent retching during the operation. When the growths are numerous and large, prolonging the operation, the anæsthesia may be cautiously maintained by pumping in more of the vapour through a tube from Junker's apparatus held at the side of the gag. It is right to mention, however, that such an important authority on anæsthetics as Dr. Silk disapproves of giving chloroform or any other anæsthetic after anæsthesia has been induced and the operation begun. Upon the importance of this Dr. Silk places great stress. Here it may be remarked that a competent anæsthetist with special experience in these cases is of very great importance. He should wait beside the patient till perfectly satisfied that he is safely out of the anæsthetic. The deaths which have occurred seem to have been in some cases due to the neglect of this precaution. While the surgeon and anæsthetist turned aside for a few minutes to attend to some other matter, thinking the operation was safely completed and the anæsthesia passing off satisfactorily, the fatal result took place from sudden failure of the heart's action.

The finger-nail operation.—Some authorities—such as Mr. Pritchard, Mr. Field, and Mr. Lennox Browne—seem to trust entirely to this method, which was first advocated by Dr. Guye of Amsterdam. There is a decided feeling, however, on the part of most specialists that this method of removal is in general insufficient, and that when employed, subsequent operations are not infrequently required. Only in the softer and flatter forms, occurring in very young children, do I think the method of scraping them away with the finger-nail sufficient by itself to eradicate the growths. The

[1] THE LANCET, Feb. 18th, 1893. See report of discussion on this subject at the Harveian Society.

Digitized by Google

finger-nail may, however, be employed with advantage for the clearing away of remnants of growths after the use of a curette or forceps. If the finger-nail treatment be employed the nail of the right index-finger should be kept properly pared, so as to be neither too short nor too long. If too long the nail is apt to bend or even break when tearing off the vegetations. The finger-nail should, of course, be scrupulously clean, and before operating it is a good plan, as proposed by Mr. Pritchard, to immerse it for a short time in rectified spirits, both for its antiseptic effect and its hardening influence on the nail. If no general anæsthetic is given, a 10 per cent. solution of cocaine should be applied to the naso-pharynx either with a spray through the nasal passages or a plug of cotton on forceps introduced from the lower pharynx. The cocaine is more efficient in adults, as we are able in them to apply it more freely and with greater safety to the walls of the naso-pharynx than in children. The child is seated in a chair while the arms and legs are held firmly by assistants, and the right index-finger is introduced into the mouth, moved rapidly backwards, and turned up behind the soft palate. The nail of the finger is then made to tear or cut through the soft tissue in the roof and back wall and from the neighbourhood of the Eustachian prominences, if any there exist. In order to prevent the patient biting the finger of the operator the first phalanx and the metacarpo-phalangeal joint should be protected by thick indiarubber tubing, or, as some operators do, by pressing the cheek of the patient between the patient's teeth on the left side. In some cases the soft palate moves backwards before the finger so as to close the way to the naso-pharynx and prevent the introduction of the finger; in such cases I have found it a good plan to introduce a uvula retractor and press the uvula and soft palate firmly but gently forward with the left hand. When the finger is well into the naso-pharynx the retractor is withdrawn.

The artificial nail.—An artificial nail of steel is used by some authorities, such as Dalby, Capart, and Bezold. It is fixed to the index-finger, and, being of course stronger than the natural nail, is more capable of penetrating and removing the growths. But I have found its use unsatisfactory owing to the impaired tactile sensibility and the increased bulk of the finger preventing safe and efficient use. Justi and Trautmann employ an artificial nail fixed on the end of a stem which is attached to the finger. Of this method I have had no experience.

Gottstein's curette.—Gottstein's curette is a triangular fenestrated instrument attached at a right angle to a long handle. The inner edge of the base of the triangle is sharp as a knife. This is the instrument which I now generally employ in removing these growths, and I have found this method more convenient and satisfactory than any other. In this my experience agrees with that of Politzer, Rosenberg, Semon, McBride, and others. In this country, when Gottstein's curette is employed, the patient is usually anæsthetised with chloroform, and lies on his back with the head hanging well over the end of a table, supported with the hands of an assistant, the back of the neck resting on a firm pillow. A waterproof cap, similar to a bathing cap, should cover the head in order to prevent the blood which flows from the nose mingling with the hair. A large towel or piece of jaconet should envelop the upper part of the body. A gag (Mason's) should be applied on the left side, well guarded with thick indiarubber tubing so as not to injure the teeth or gums. The teeth should be examined, and if a loose tooth is found care must be taken in case the gag should separate it altogether, and endanger the patient by the tooth slipping into the larynx during the operation. The chloroformist is at the head of the patient, the operator on the right side, and an assistant for attending to the gag and sponges at the left side. A dozen small honeycomb sponges, clean and aseptic, secured on sponge-holders, should be at hand. The finger is introduced into the naso-pharynx to determine the quantity, situation, and character of the growths. The triangular end of the curette is then introduced behind and above the soft palate, with its convexity upwards and backwards, avoiding the lateral walls, until the blunt edge of its base is in contact with the posterior edge of the nasal septum. The handle is now grasped firmly, the curette is pressed well down upon the roof of the pharynx, and drawn backwards and then downwards, so that the sharp edge is made to sever all the vegetations in its sweep. With the ordinary curette the vegetations, removed in this way, are either expelled through the nose, mingled with the blood, or are mopped out with the sponges, or are swallowed.

A useful modification has recently been introduc which there is an arrangement with two sharp pro front of the triangular steel frame for detainin vegetations cut off with the sharp edge of the c I usually employ three strokes before withdrawi curette, and then, with one sponge quickly introduce another into the pharynx, the blood is mopped up assistant. Once more the cavity is examined wi finger, and if any growths are still found the is again introduced, or the finger-nail may be su If the curette is employed without an anæsthetic the should be seated on a chair having a low, broad-cu back, over which the head is bent and supported assistant. After cocaine has been freely applied walls of the naso-pharynx, the tongue is pressed dov a spatula, and the curette is employed in the same as when an anæsthetic is used.

Hartmann's curette.—Hartmann's curette is prefe some operators, such as Krause of Berlin, and Bru Bradford. The force is applied laterally and not posteriorly, as with Gottstein's curette. An ana is rarely used by those who employ this inst The patient, if a child, sits upon the knee trained assistant, who, with the legs and left fixes respectively the patient's legs and arms, the same time holds the patient's head firmly, with t of the right hand placed firmly against the patien head. In this way the head of the patient is held im against the chest of the assistant. Light is reflec the throat, the tongue is depressed by a spatula, curette is pushed up into the naso-pharynx. It pressed on the posterior wall and roof of the naso- then it is moved, as on a pivot, to one of the later and the edge of the curette is made to sweep acro opposite side with firm pressure so as to sever an the vegetations in its course. My limited experienc method of operating has not impressed me favourab not think it is so efficient as Gottstein's instrum usually leaves untouched the growths in the front p naso-pharynx, while I think it is apt to injure the E prominence and excite middle-ear disease. My fr Seright, however, who frequently witnessed it Krause's hands, believes it to be a very efficient inst

Golding-Bird's curette.—This is an oval fe instrument connected with a long stem bent at ra than a right angle near the fenestra. The cutting o edge, instead of being on the inner aspect of the bas on the lower side. It is applied in a similar wa stein's curette, but on account of the position of th edge it penetrates more deeply and is particularly s scooping out the growths situated at the junction c and back wall of the naso-pharynx. Whilst I ha much experience of this instrument it seems to me able one.

Löwenberg's forceps and modifications.—Many prefer the use of forceps devised by Löwenberg an at different times by various workers. Up till a ago my own method was to operate with forceps, a them particularly suitable with the patient in posture. There is no doubt that when patien friends shrink from the use of a general anæst mode of operating is probably more convenien painful than other methods. With the patient s chair, and the head, arms, and legs firmly hel reflected in the ordinary way into the pharynx. blades closed the forceps are introduced as posterior wall of the pharynx. The blades pushed up to the roof of the naso-pharynx, wh widely separated and made to lay hold of one or adenoid projections, which are brought away cutting and partly by traction. The forceps way be introduced three or four times at one si blades of the forceps should have their cutting and behind, while there should be a free space as to lessen the chance of catching hold of th the nose. Owing to the anxiety of the operator septum the growths immediately behind it escape the forceps. Mr. Hovell (who discards or scraping instruments) has modified the forc the two cutting edges are circular and do no to edge, but are so arranged that the one bla the other, their action being thus that of a claims for this modification that it avoids the ri away shreds of mucous membrane or of injuring

Digitized by Google

Whatever forceps may be used it is important that they should not be too large. Many of those sold by instrument makers are much too large for children, in whom, as you know, most of the cases of post-nasal growths occur. Just as after the curette operation, the finger-nail may be used with advantage to remove any fragments which may remain after the forceps have been employed. If the operation is performed during anæsthesia the patient should lie on his back with his head on a level with the body. A gag is used as in the curette operation, and the index-finger of the left hand is introduced into the naso-pharynx with the back of the hand downwards and forwards so as to guide the blade of the forceps to the individual growths. In this way the forceps are introduced several times and the growths individually pulled or cut away until, as informed by the finger, they are all removed. This sounds very satisfactory, but in practice it is often found to be no easy matter to accommodate the index-finger and the blades of the forceps in the small naso-pharynx of a child so as to manipulate freely, and the efforts to do so often lead to much bruising and injury of the parts. When operating with the forceps, while the head hangs over the end of the table, especially great care should be taken to avoid laying hold of the septum. I hold a skull before you in this dependent position, and you will see how very apt it is for the forceps to lay hold of the septum. Indeed, in this position the use of the forceps is unjustifiable unless one is able with the left index-finger to guide accurately the blades of the forceps.

Meyer's ring-knife.—We must not omit to mention the method of operating adopted by the late Professor Meyer of Copenhagen, to whom the profession is under a deep debt of gratitude for being the first to draw attention to the existence of these growths in the naso-pharynx. He operated through the nasal passages and used a ring-knife having one sharp edge, attached to a steel stem, which is introduced through the wider nasal passage. When the knife has reached the naso-pharynx it is turned horizontally if the growth is in the roof. The left index-finger of the operator is introduced through the mouth into the upper pharynx, and the ring-knife is pressed up so as to encircle one of the growths, when the knife is drawn forwards, severing the growth. Few operators have followed this method of Meyer.

After-treatment.—It is well after an anæsthetic operation that the patient be turned on his side, retaining the head on a level with the body, or somewhat raised, while the gag is kept between the teeth for a minute. Some operators, in order to prevent bleeding, maintain pressure on the walls of the naso-pharynx for a few minutes with a sponge or folded gauge or curved forceps. In most cases, however, blood is swallowed in considerable quantity, frequently exciting vomiting, the vomited matter consisting of blood mixed with the contents of the stomach. It is well always to warn the friends that vomiting is likely to take place, if it has not already done so, and that someone should be at hand beside the patient ready to help. Pieces of ice placed in the mouth, or even in the nostrils, after the patient has regained consciousness tend to check the sickness. The ice may be given at intervals for twenty-four hours, during which the patient should abstain from *hot* liquids or solids. Bleeding of an alarming nature is very rare, but I have been twice sent for, a few hours after the forceps operation without an anæsthetic, owing to pretty copious bleeding. Pressure upon the roof of the naso-pharynx by means of a fold of cotton moistened with a styptic solution, introduced with forceps, easily controlled it. The patient should rest in bed for two days and keep the house for a week after the operation, during which no local treatment of the nose with douche or syringe should be employed. These precautions are especially important in damp, cold weather, so as to avoid middle-ear inflammation, which I have, however, almost never found in my own practice to follow this operation. There is no doubt that injudicious nasal treatment after the operation is apt to excite inflammatory mischief in the middle ear.

Enlarged tonsils.—Not infrequently these growths are found associated with hypertrophied tonsils, which are often regarded erroneously as the sole cause of the nasal obstruction and the deafness. Probably the safest plan is to first remove the enlarged tonsils, without, if possible, an anæsthetic, and then, after the healing process is complete, the post-nasal growths should be operated upon. Some specialists remove the tonsils and the post-nasal growths at the same time under an anæsthetic, and in certain cases this is perhaps the best method. To produce so extensive a bleeding surface, however, might in some persons be attended by considerable risk, partly from the bleeding and partly from the greater risk of septic infection.

Mouth breathing after operation.—If mouth breathing continue in spite of the operation, and we are confident that the post-nasal growths have been thoroughly eradicated, we should carefully examine the nasal passages in order to make sure that no obstruction exists there. If, in either side, the inferior spongy body is found to be enlarged or hypertrophied, cauterization with the galvanic cautery or chromic acid may be required. In mild forms of obstruction a prolonged but careful use of an alkalo-saline solution with a spray apparatus or a suitable syringe may prove sufficient. If the obstruction be due to spurs upon the septum or deflections, these may require operation, but such forms of obstruction are not common in childhood. If, after the mechanical impediment of free nasal breathing has been removed, the mouth breathing still continues, means must be adopted to help the person to overcome this habit. The simple plan should be first tried of causing the patient to sit still for fifteen minutes, twice or thrice daily, during which he studiously keeps the mouth closed and breathes through the nose alone. If after a time this prove insufficient, an appliance should be provided consisting of a small indiarubber cup, on which the chin rests, the cup being kept in position by means of bands secured round the head. This should be worn for a time at night so as to keep the lower jaw from falling. Or we may use an indiarubber band with a mouthpiece of soft leather secured round the head during sleep, so that the leather mouthpiece covers the mouth and compels nasal breathing. Another plan, which I have known a female patient to adopt, is to retain the lips in contact by means of long strips of sticking-plaster. Some writers ridicule the use of these aids to nose breathing, alleging that if the nose and naso-pharynx are really free from obstruction, the breathing will naturally become nasal without any such contrivances, and that if there is defective nasal breathing we shall find a mechanical cause in the nasal cavities, which must be removed by suitable treatment. I am, however, disposed to differ from those writers. I have undoubtedly seen cases remedied by these artificial helps, where the mouth breathing had persisted after ample breathing space had been secured in the nose and naso-pharynx.

General treatment.—In connexion with post-nasal growths there is not unfrequently a constitutional flaw, such as the strumous or anæmic condition. Iron tonics, cod-liver oil, plenty of fresh air, and a sufficiency of nutritious food may, therefore, prove important additions to the operative treatment.

THE PREPARATION OF ANTIRABIC SERUM AND THE METHOD OF DETERMINING ITS STRENGTH.

BY PROFESSOR GUY TIZZONI AND DR. EUGENE CENTANNI.

I.—ACCOUNT OF SERUM-HEALING IN RABIES.

BABES and LEPP,[1] when treating of vaccination against rabies, have tried to determine whether with the blood of a vaccinated animal it is possible to transmit immunity from that disease to another animal. In spite of all the experiments performed to settle this question, they tell us nothing of those practised on the rabbit, so as to enable us to judge of the value of the final result of the experiments, or whether misleading results had been obtained, either through the infection having been brought about by an unreliable method, such as that of subcutaneous injection, or through all the animals having died too soon from an intercurrent disease for the full results to have been observed. Nor, on the other hand, can those performed upon the dog (four in all) have an absolutely trustworthy value, since the two successes obtained upon this animal are reduced in reality to one single experiment in which the animal was infected by trephining. Nor can another experiment be

[1] Recherches sur la Vaccination Antirabique. Annales de l'Institut Pasteur, Nov. 7th, 1889.

Digitized by Google

accepted as being of proved worth, in which, though the animal survived the infection a long time, it had been determined by a method so little reliable as is the infliction of the bite of a rabid dog. Not until four years after these researches were made known did we commence the publication of a long series of experiments, all carried out in this institution, and by which we are not only able to state that the question of serum-healing in rabies has been studied, but we are able to declare, further, that it has been definitely solved. All these researches were made upon the rabbit because it was possible by such means to give to the experiment a wider scope, but also—the rabbit being an animal much more susceptible to rabies than is the dog (?)—the results obtained upon it would have a greater value.

In a former work it was shown[2] that the serum of vaccinated animals is able, not only to destroy *in vitro* the pathogenic power of the virus of rabies (*virus fixe*), canine virus of the streets during the process of transition (exaltation) and also when fixed, but is also capable of preserving the rabbit from rabies and of hindering the development of the disease when the infection has been made twenty-five hours before the treatment. It was proved that the serum of the rabbit has in that animal a stronger protective action than that of the dog; that the active substance of this serum in the presence of magnesium sulphate behaves like a globulin and is not dialysable; and that it is precipitated with alcohol and with neutral salts, but loses in this precipitation part of its activity. Later, with a view to extending our researches on serum-healing in rabies and of drawing from these the greatest results possible, as much for the benefit of science as for advantage in practice, a new method of vaccination against rabies was sought which should give a higher degree of immunity than that obtained by Pasteur's method. Taking as a starting-point the experiments of Eusebius Valli,[3] we established satisfactorily that the gastric juice at first effectively weakens and at last completely destroys the pathogenic power of the virus of rabies, whilst at the same time it does not interfere with its vaccinating power. Therefore, following this path patiently with a numerous series of experiments, we succeeded[4] in determining the principles of a new method of vaccination—with virus weakened by gastric juice—a method of vaccination which in honour of Valli, from whom we have taken the idea, and to distinguish it further from the French method devised by Pasteur, we have designated the "Italian method of vaccination against rabies," the superiority of which was at once clearly demonstrated by the positive results obtained by us in the vaccination of the rabbit against infection with the virus of the dog, and by the possibility of protecting that animal comparatively easily even against subdural infection with a fixed virus. A serum of the highest protective power being obtained by this method, it was easy to demonstrate with it in successive and unvarying experiments that the alcoholic precipitate of the serum of vaccinated animals serves, not only to hinder the development of the disease when it is injected a little before or after the infection practised under the dura mater or on the nerve, but leads to the same result even when the virus is infected long before—i.e., during the period of incubation (seven to fourteen days as against the canine virus)—and even succeeds in stopping the course of the disease when the injections are practised[5] after the first symptoms have shown themselves. A demonstration more absolute than that of the efficacy of serum-healing in rabies and the advantages which it has over vaccination with Pasteur's method can certainly not be offered. Lastly,[6] we proved that the results obtained in the rabbit by the Italian method of vaccination against rabies could also be obtained in larger animals—viz., dogs and sheep—and that from the species of sheep employed could be drawn a protective serum sufficient in quantity and curative power for all pr requirements. We succeeded in determining the dos injected into those animals in order to confer im upon them—a decided step forward—whilst we wer to trace the curve which represents at various per the vaccination the quantity of the protecting subst the blood, thus indicating the best time at which to t blood for use.

After the publication of the first of our memoir serum-healing in rabies, Babes communicated to the national Congress of Hygiene in London (August, 18 results of experiments made upon man with serum c partly from a protected man and partly from a pr dog. But to these observations great value can attached—it may be because they are wanting in a experimental basis or because they were made accor the method of Pasteur. Shortly afterwards appea extended work of Babes and Cerchez[7] on the sub ject, in which were related two new successf obtained on the dog with the serum of blood of va dogs, but for the rabbit the conclusion was again at "que le sang du chien réfractaire inoculé aux avant ou après infection avec le virus de la rage, n pas sensiblement sa virulence." So, while our fi appeared at a time when, with regard to serum-he rabies, science could only point to the success c on the dog, it demonstrated absolutely that the s the blood of a vaccinated animal injected into th either before or after the infection hinders the ment of rabies, and enabled us at last to un the principal property of the protective substa tained in the serum; whereas in the work of Babe appeared after ours, the possibility of saving the l means of the serum of a vaccinated animal was puted. A final memoir upon serum-healing in r been published by Babes and Talasescu.[8] The in this work record results better than those obtaine preceding experiments: they were completely succ the rabbit, and were able to inject largely the qua serum (into a medium-sized animal of 5·0 c.cm., s times up to about 15 c.cm.), yet here, as in the experiments, any plan of obtaining results always and favourable is still wanting. Moreover, a the experiments related, on two or three only ca opinions be formed, the other animals having died, either after a few days from accidental c from something or other not well determined, in seems to recognise the symptoms of a wasting ra to the serum not conferring sufficient immunity virus of rabies is transmitted from dog to do the most recent results obtained by the authors be relied on to confirm a fact which is now a patrimony of our science, nor do they in any wa the more important question which to-day sc practice in turn demand should be solved — t determine the precise conditions on which the is constantly verifiable to investigate the me its production, and finally to establish all tho which serum-healing in rabies can be entered up tice, no longer blindly and guided only by the ca physician, but illuminated even in the smallest by the light of experiment. It is precisely to th our studies have been directed, and, taking ou researches as a starting-point, we have tried to acq result in those points in which they seemed to be to give an account of some exceptions v time to time were met with in the preceding e and, lastly, to solve other particulars of the quest ledge of which we have believed to be indispen passing from animals to the application of the t man.

II.—MODE OF PREPARATION AND PRESERVAT ANTIRABIC SERUM.

We shall in this part study the following poi number of injections, the length of the period of the quantity of material to be injected, and the attenuation necessary to obtain an immunity high—it may be with the first series of i

with a series of progressively increasing strength; (2) whether the strengthened injections can gradually raise the original immunity obtained with the first series of vaccinations, and up to what limit; (3) the interval which should be allowed to elapse between the different series of the strengthened injections in order to obtain the best results from them; (4) the most favourable moment for taking the blood of a vaccinated animal; and (5) the mode of preservation of the antirabic serum which for facility, economy, and safety best corresponds to clinical needs. All these questions have been studied by us on the sheep, which we were aware, through our preceding researches, was the animal most adapted to furnish material of the highest protective power necessary to satisfy the needs of practice.

1. *Number of injections, length of period of vaccination, quantity of material to be injected, and the degree of attenuation necessary to obtain with the first series of vaccinations a fundamental immunity of sufficiently high degree.*—In this respect we have been able to confirm and also better to determine much that we had established in our preceding experiments. Thus in four other sheep we have obtained by means of the constant mode during the first series of vaccinations serum of the highest protective power, and have determined more exactly that to arrive at this end seventeen injections in twenty days must be made, each injection consisting of 0·25 gramme of the nerve substance properly weakened by gastric juice, as described in our previous work, for every kilogramme of the animal's body weight. In fact, with the serum of these animals we succeeded, by the *constant mode*, in saving rabbits from subdural infection with an infecting unit of the canine virus (as demonstrated elsewhere), not only when there were injected under the skin, twenty-four hours before infection, considerable quantities of serum (5 to 0·33 c.cm.), but also when the serum injected was in the proportion of 1 part of serum to 25,000 of body weight, as shown in Table I.

The establishment of the data given in the series of injections was also more important than during the first vaccinations, in order not to be always obliged to have recourse to fresh animals in the preparation of the antitoxin of rabies, which, not possessing any original immunity, would have at least to undergo a longer series of injections in order to give material as powerful as that of the revaccinated animals. The numerous trials patiently carried out to this end on our sheep have demonstrated to us that in revaccination the best result with respect to the degree of the protective power of serum is met with where ten injections have been administered in twelve days, each injection consisting of 0·25 gramme per kilogramme of the weight of the body of nerve substance duly diluted. In such a way we succeed in obtaining a serum which, in the quantity of 5 to 2 c.cm. for subcutaneous injection, and finally in the proportion of 1 to 25,000 compared to the weight of the body, invariably saves the rabbit from subdural infection with the canine virus administered twenty-four hours afterwards (see Table II.).

In these experiments, then, we have been able to demonstrate clearly that the quantity of the material which is injected is of very great importance in the production of the protective substance of the serum, but also that, beyond a certain limit, the quantity of nerve substance, more or less diluted, which is introduced by these injections is harmful rather than a help. Thus, taking from ten to twelve as the number of the progressive injections, and each time injecting one-fourth rather than one-third of a gramme of nerve substance per kilogramme of the body's weight, we find that the serum collected has a very much lower strength—about half that of the preceding case. In fact, not one of the rabbits injected under the skin with this serum in the proportion of 1 to 25,000 compared to the weight of the body resisted the subdural infection with the infecting unit of the canine rabic virus; and with the proportion of serum indicated we succeeded in saving these animals when the dilution of the virus was only increased twofold, keeping fixed the quantity of emulsion which is injected under the dura mater, which was equivalent to lowering the strength of the serum by about one-half (see Table III.). Our researches have also resulted in showing the very great influence which the degree of attenuation of the virus has upon the production of the protective substance of the serum—an influence which necessarily appeared greater when, in the hope of shortening by some days the period of vaccination, we increased contemporaneously the dose of the nerve substance injected each time—carrying it, that is to say, to one-third of a gramme per kilogramme of the body weight. In the following experiments with serum taken at the same period of time from Sheep I., II., and III.—all revaccinated with eight injections made in from eight to nine days, being infected each time with one-third of a gramme of nerve substance per kilogramme of the weight of the body, while in the last four injections the mass of the virus was not subjected to any digestion with gastric juice, hence virulent in the highest degree—we have found that the subcutaneous injection of the serum of the first sheep in doses of from 2 to 3 c.cm. saved the rabbits from subdural infection with the infecting unit of the canine virus in the proportion of 62 per cent. We have found that that of the second and third sheep, in the quantity of 2 c.cm., gave under the same conditions a mortality of 100 per cent.; and, finally, that that of the third sheep, given in the quantity of 5 c.cm., gave, against the same infection, a percentage of cure of only 66, as will be seen from Tables IV., V., and VI.

The influence of the conditions indicated upon the production in the serum of the antitoxin—i.e., the number of the injections, the length of the period of revaccination, the quantity of nerve substance injected, and its degree of attenuation—appears hence to be more evident when the results obtained on the same animal in two revaccinations are compared, as in the second and third revaccination of Sheep I. (see Tables II. and IV.)—the first comprising eight injections in eight days with a dose of one-third of a gramme per kilogramme of nerve substance (in the four last injections not digested at all), while in the second there were ten injections in twelve days with a dose of a fourth of a gramme per kilogramme of nerve substance and with all the virus more or less digested for a considerable time. Meanwhile, with this second manner of revaccination, which we hold to be the best, we have 100 per cent. of cures; whilst when the quantity of serum is to the weight of the body as 1 to 25,000 we obtain with the first hardly 62 per cent. of cures when from 2 to 3 c.cm. of serum are injected—a quantity that is thirty-five times as great as that which was given in the preceding case. Hence it stood confirmed by our researches what had been affirmed in one of our earliest works upon rabies—that the virus of rabies[10] in its attenuation by the Italian method—that is, with half the digestion performed by gastric juice—whilst it loses its virulence by degrees, does not lose—or only very slightly—its vaccinating power. We may add to this that the virus of rabies not submitted to any digestion may be hurtful, not only from the absorption of poisonous products, but also because the materials injected in that condition can be more easily absorbed. It is worth while, further, to put forward another very great advantage which vaccination with the virus digested by gastric juice must have over that in which the nerve substance diluted by means mostly physical is injected diluted only with water, as is practised in the Pasteurian method. The methods of vaccination and revaccination which we have found to be the best are better tolerated by the animals. These, especially at the first injections, are affected by slight shock; they remain more willingly in the lying position, eat less, and show that their movements are only slightly hampered, especially in the hinder part, perhaps from the mechanical distension of the skin produced by the injection, generally performed in the region of the flanks; but soon, even during the process of vaccination, they regain their vivacity and the appetite. The weight of the body is lowered during the vaccination by 3 or 4 kilogrammes, but after this has been accomplished it increases rapidly, so that the injections appear to have a fattening effect. Thus, Sheep I., thirty days after the first strengthened series, rapidly increased in weight from 18·380 to 21 kilogrammes; Sheep III. went from 28 to 36 kilogrammes only twenty-six days from the date of the vaccination.

2. *Whether the strengthened injections are able to gradually raise the original immunity obtained with the first series of vaccinations, and up to what limit.*—This also was a very important question; it was of the greatest interest to know whether, after deducting the time necessary for the vaccination, there could be obtained a material as strong again as that found with a successively strengthened series, or whether with these, at a standard which was always increasing, one would be able to have the serum of a protective power always raised to a corresponding degree. Such a

question, then, was very important, not only in connexion with the cure of rabies, but also with general considerations on vaccination made with a view to find curative serum and with the solution of the problem at present so keenly debated and of such interest from the therapeutical point of view, whether the intensified injections are able to increase without decreasing the protective power of the serum, or whether the protective power of this is able to combine only within determined limits with the poisoning power of the vaccinating material used. The question is excessively important, and we are able to pronounce upon it in a concise and general way. In so far as the infection of rabies is concerned, we are inclined to hold, through observations made on many animals and in many series of experiments, that in this infection a series of vaccinating injections, when they are made of material of constant quantity and power, gives always, as many times as it is repeated on the same animal, a serum of the same degree of activity. We have seen in part in the reports given above (Table I.)—and it will appear more clearly in the experiments which we report further on (Tables XIII. and XVI.)—that already with the first series of vaccinations upon a fresh animal we can have at one stroke the highest type of protective serum, and that on repeating successively on the same animal at various times one and the same series of vaccinations, at intervals varying from two to five months, the protective power of the serum is maintained at a constant level. And, for this reason, we are inclined to believe that in rabies the power of the blood may be a power exclusively passive, in the sense that we do not treat of a special function which the organism may acquire and render perfect under the stimulation of the modified virus; most certainly the substance to which the serum owes its activity proceeds directly from the material which little by little pours itself out in a circle near the subcutaneous deposit of such virus. This is certain: We cannot expect an increase of value in our serum by repeating the series of vaccinating injections of animals which have been previously deeply and repeatedly vaccinated; we ought to trust rather in the progressive improvement of the vaccine itself, rendering it more supportable and more concentrated.

3. *The interval which should be allowed to elapse between the different series of the intensified injections in order to obtain the best results from them.*—With regard to this question we have been able to establish that the sheep is sufficiently tolerant of these injections of rabid virus, and that without

Digitized by Google

exhausting the animal too much the vaccinations may be repeated every two or two and a half months. The only object of leaving a sufficient time between each revaccination is not to stimulate to excess the subcutaneous connective tissue, in order not to run into any difficulty by making the revaccinations too soon, by beginning a new series before the irritative effects of the last have faded away or are repaired; besides which, there are the not very serious effects which must necessarily be produced in the preceding series by the mechanical and chemical action of the injected emulsion—as a result of which the absorption of the active material must be made with great difficulty. And we have often said the rapid and complete absorption of the vaccine on the part of the connective tissue is an essential and indispensable condition because the protective power of the serum can be raised at a given moment to much higher degrees, since it is natural that the suppuration of the infected part and other complications may detract from the wealth of antitoxin in the blood, because with this are separated, destroyed, or eliminated the useful part of the injected vaccinated material, and the organism is thus deprived of a portion more or less great of the products to which the serum owes its protective and curative properties. To collect on a sufficiently large scale the nervous system of a rabid animal, and to keep it aseptic amidst all the manipulations to which it must be subject up to the moment in which it is injected under the skin of the sheep, we are now provided with satisfactory appliances, and after a long trial we have met with the best means of avoiding any complication in the injection of vaccine—above all, the suppuration of the part injected.

4. *The most favourable moment for taking the blood of a vaccinated animal.* — We have already expressly occupied ourselves with this question in our preceding work,[11] but during the present and last years, having gathered much material from our studies, and being in possession, as we shall see in the following part, of methods more exact for the determination of the protective powers of the serum, we have not wished to neglect to review them, but to extend and definitely settle this point of the question, it being so important to gain from the vaccinated animals the best results possible in the serum-healing treatment. Nor in order to establish these data have we been able in any way to have recourse to as much as has already been made known in regard to the best moment for taking the blood in other infections, especially in tetanus and in diphtheria, because, besides the very great difference in the duration of the period of incubation of these maladies compared to rabies, there exist considerable differences in the methods with which in each of them the fundamental immunity is obtained and the strengthened injections are practised. In rabies, in fact, in order to obtain the strength of the acquired immunity, instead of a single injection, and with a cultivation made artificially, we make a series of injections with a virus cultivated by natural means much stronger and weakened according to a descending scale; therefore, wishing to apply to this malady what has already been established for another, it cannot be said *a priori* whether the computation of the days which should pass between the vaccination and the moment of taking the blood ought to be made from the beginning, from the middle, or from the end of the strengthened injections. Nor at first can it be judged what influence the heterogeneous injected materials may have upon the protective value of the serum. The researches pursued with this idea have fully confirmed what we had previously established—viz., that the most opportune time for practising bloodletting and collecting the serum of animals vaccinated against rabies is the twenty-fifth day starting from the last injection of the series of revaccinations. Besides, we have been able to determine that whenever the strengthened injections are made according to the proper rules and are perfectly successful the accumulation of the protective material in the blood has in the vaccinations against rabies a period sufficiently long, by which, not looking for the highest terms of the power of the serum, it would seem that little or no difference exists in the protective value of the same serum taken at various times after the vaccinating injections. Thus, taking the blood from the same animal ten and twenty-five days after a revaccination—the first time in small quantity (so as not to influence by a too abundant subtraction of antitoxin from the results which would be obtained at the second bl we succeeded equally with 5 c.cm. of serum injected the skin in saving all the rabbits infected twenty-fou afterwards with the canine virus; but, contrariwise with the serum of the blood collected at the twenty-fi we also obtained the same effects with a proportion o to the weight of the body of 1 to 25,000, with th collected on the tenth day we arrived scarcely at portional quantity of serum last indicated only sav the animals infected, as may be clearly seen from to the two parts of Table VII.

5. *The mode of preservation of the antirabic serum for facility, economy, and safety best corresponds to needs.*—It is certainly very important to find them preserving the antirabic serum against any contamina in a form which renders its despatch easy and in w serum loses nothing of its protective power. With this it is found, as with tetanus,[12] that the desire compassed perfectly when the serum is first in volume by distillation at 38° C. *in vacuo*, where dried *in vacuo* over sulphuric acid. Numerous cor experiments have demonstrated, in the case o that we obtain upon animals the same result when use of fresh serum as when a corresponding qu dried serum is injected, even if this has been for some months, so that now in our experiments either serum indifferently. In the sheep the proportic serum to the liquid serum of recent cultivation one-third of the original weight, since 7 and antitoxin correspond to 100 c.cm. of serum. T serum has the appearance of red and yellow sca dissolve easily in ten times their own weight preserved in a coloured phial and protected damp by a perfect-fitting stopper, it keeps its prot perties unaltered for a very long time. It there itself very well to the needs of practice.

SUBMAXILLARY EXCISION OF HA TONGUE.

By W. G. SPENCER, M.S., F.R.C.S. En
SURGEON TO OUT-PATIENTS AND TO THE THROAT DEPA WESTMINSTER HOSPITAL.

OPERATIONS on the tongue and floor of the epithelioma have become so much less dangero immediate mortality therefrom has almost vanishe for well-selected cases. Unfortunately, the fin regards cure is yet far from successful, and ul considerable size are too often followed after malignant disease of the submaxillary lymph The method often adopted at the present time half the tongue by scissors and then to shell ou small incision any submaxillary lymph glands wh felt to be enlarged. There are thus left the passing from the affected tongue across the mouth, through, or behind, the mylo-hyoid mus remainder of the submaxillary lymph glands w at the time sufficiently big to be felt. But gl the size of a haricot bean may not be felt before t for they lie between two layers of fascia or lobules of the submaxillary salivary gland, and by a more or less thick layer of subcutaneo only sign of enlarged glands before op be slight tenderness as compared with the yet after removal all the submaxillary lymp found increased in size. Formerly, surgeons ascribe such tenderness to simple inflammation likely now to hold such a view in the light g more thorough microscopic examination of suc the careful observation for some time afterw wherein such glands have been left behind. aim to take away the whole diseased area complete way than would have been wis

days, when the immediate mortality after the operation was so great. The typical operation, whether it include the glands below the jaw, those in the axilla or in the groin, is the same—viz., the excision of the cancer, together with a wide margin of apparently healthy tissue, and of the lymphatics running from the area removed as well as the glands to which the lymphatics go, all in one piece, so that none of the disease shall be overlooked. The operation adopted is briefly as follows:—1. Anæsthetic: nitrous-oxide gas and ether; later chloroform. 2. Skin incision: (*a*) vertically from the point of the chin to the hyoid bone; (*b*) horizontally along the hyoid bone to the great cornu; and (*c*) obliquely upwards and backwards to the outer border of the sterno-mastoid opposite the angle of the jaw. This skin flap is turned up on to the face. 3. Division of the superficial and deep fascia with the platysma along the line of the skin incision. These structures, containing the submaxillary, lymph, and salivary glands, are then raised from the muscles and hooked upwards. 4. Ligature of the lingual and facial arteries. The vessels are cut across after being tied on the proximal side, and the distal end clamped. The lingual is exposed in the digastric triangle by separating the fibres of the hyoglossus with forceps to avoid pricking the lingual vein, which swells up in front of the artery of the living subject. Moreover, there is thus no possibility of wounding the pharynx should the patient make a sudden expiration. By hooking up the submaxillary gland the facial artery is straightened out, and is, therefore, easily ligatured in front of the posterior belly of the digastricus. 5. Division of the fascia by cutting along the lower border of the jaw, the distal end of the facial artery and vein on the face both needing a ligature. 6. Separation from the jaw of the genio-hyoid and mylo-hyoid muscles along with the mucous membrane of the floor of the mouth, from the middle line to the angle, by keeping the edge of the knife applied to the inner surface of the bone. 7. Removal of the half of the tongue with the floor of the mouth and glands through the submaxillary opening. The tongue is first split down the middle, and by means of a ligature through its tip drawn out well into the submaxillary triangle, then cut away from the hyoid bone along with part of the anterior pillar of the fauces. 8. The wound is covered with iodoform filled with strips of gauze, the ends of which hang out of the mouth, and the skin flap fixed in its former position by a continuous suture.

The chief point of the operation is the complete removal of the submaxillary and sublingual glands along with the lymphatics running to them from the tongue. Experience has shown how impossible it is to detect by digital examination early disease in glands. The microscope will frequently bring to light a small focus of disease in glands apparently unaltered. There is no need to divide the jaw unless it be actually invaded by the disease; a preliminary tracheotomy is not wanted, for, the arterial supply having been controlled, there is only venous oozing to contend with when the tongue itself is being divided. The objection raised as to the greater danger in opening a free communication between the mouth and neck is now unimportant, since the treatment after operation by iodoform crystals has been introduced as well as Whitehead's plan of urging the patient to get up as soon after twenty-four hours as possible. There is sufficient room also to remove the soft palate or tonsil if necessary. The kind of case in which this operation must fail is illustrated by the following one, which is also worthy of note by reason of the sex and age of the patient. A governess aged twenty-three, to look at the picture of good health, had an ulcer opposite the lower molar teeth. In two and a half months from the first occurrence of the ulcer an epithelioma had involved half of the tongue throughout its length, the floor of the mouth, the adjacent portion of the soft palate, and the surface of the tonsil. No enlarged glands could be felt, but after removal evidence of disease, mainly microscopic, was found. The site of the operation healed soundly and the patient regained clear speech, only to fall a prey to recurrence deep in the neck from which she died within ten months of the beginning of the ulcer. Her father had died eight years before from cancer of the throat (? larynx) after suffering for two years.

MR. JAMES WIGG, L.R.C.P. Lond., has been elected a member of the St. Pancras Vestry for Ward 3 at a by-election.

LABORATORY NOTES ON THE BACTERIOLOGY OF DIPHTHERIA.

BY E. B. SHUTTLEWORTH, PHAR. D., F.C.S.,
BACTERIOLOGIST TO THE BOARD OF HEALTH, TORONTO, AND PROFESSOR OF BACTERIOLOGY, TRINITY MEDICAL COLLEGE, TORONTO.

A CONSIDERABLE amount of bacteriological work relating to antitoxin experiments was performed in the laboratory of the Toronto Board of Health during the closing months of 1894, but it was not until Feb. 1st last that the examination of diphtheria exudates was carried on in a regular and systematic manner. The importance of such investigations was clearly demonstrated by the results obtained in the hospitals for infectious diseases in Berlin and Paris and by the extensive researches of the Health Department of New York. It was therefore determined by Dr. Sheard, health officer of Toronto, that similar work should be undertaken in connexion with the isolation hospital, an institution entirely under city control in which the greater number of patients are the victims of diphtheria. The objects sought were: (1) to confirm clinical diagnosis and determine doubtful cases; (2) to distinguish between cases of true diphtheria and those caused by cocci, so that patients affected by the latter could be isolated and more speedily discharged; (3) to demonstrate the absence of the specific bacillus from the respiratory passages of convalescents from true diphtheria, with a view of shortening the usual twenty-eight days' detention in the hospital; (4) to assist in the diagnosis of outside cases, thus saving isolation and disinfection, with their attendant inconvenience and expense; and (5) to afford a means of contributing towards a knowledge of the disease. The purpose of this paper is that of presenting a brief account of the work performed and of summarising such facts as seem likely to be interesting or useful. To this end the same general plan has been followed as that adopted in the joint report of Dr. Park and Dr. Beebe of the bacteriological laboratory of the New York Health Department, and presented to Dr. Herman M. Biggs, chief pathologist.[1] Results may in this way be more advantageously compared than with those of Berlin and Paris, where a type of disease of greater severity than that in either New York or Toronto seems to prevail.

From Feb. 1st to July 1st there were admitted to the isolation hospital 188 patients said to be suffering from diphtheria. The records also embrace, for the same time, sixty private cases in which the exudates were submitted by city physicians. The details of these 248 cases are complete so far as the examinations are concerned and are included in the statements made as to organisms present, but as these outside cases could not be readily traced no further particulars were sought. With regard to the hospital cases it may be assumed that the clinical diagnosis was sufficiently conclusive to warrant the admission of the patients, and it may also be noticed that, as most of them belonged to the poorer classes, they cannot be considered as being amongst the most hopeful. In other words, the hospital clientage may be taken as consisting of apparently pronounced cases, with an unfavourable history, and any statistics gathered from such records will certainly not lead to an under-estimate of the diseases commonly classed as diphtheria.

Collection of the exudate.—The infected material is collected by the attending physician by passing a swab firmly over any patches of visible exudate on the tonsils or the pharynx, and is at once sent for examination to the laboratory of the Health Department. This method is deemed preferable to that commonly practised, in which a culture is at once made by the physician, as it affords an opportunity for the bacteriologist to make an examination of the exudate as well as the culture, thus forming a check of some value and also often enabling a reliable diagnosis to be at once pronounced. Another advantage is that the condition of the culture medium can be guaranteed and the manipulation be in more experienced hands. The swabs are prepared by cutting No. 15 steel wire into six-inch lengths, roughening one end by a few strokes of a chisel-edged hammer, and firmly winding on a little ordinary cotton-wool so as to make an application of about a quarter of an inch in diameter. The other end of the wire is then passed through a tapered cork of

[1] New York Medical Record, vol. xlvi., Nos. 11 and 13.

Digitized by Google

the best quality, which fits into the non-lipped mouth of a stout, well-annealed test-tube of 15 mm. internal diameter by 100 mm. in depth (say, five-eighths of an inch by four inches). The object should be that of preventing the infected material from soaking into the swab, and preference is therefore given to ordinary cotton-wool rather than the absorbent kind hitherto recommended. A cork will also be found an improvement on the usual plug of cotton-wool, and is practically a sufficient protection from extraneous germs. The tubes containing the swab are sterilised by one and a half hours' exposure to a dry heat of 150° C. The swabs are supplied free to any physician requiring them.

Culture. — Experiments have been made with various media; but Löffler's blood-serum mixture, prepared by the quick method, has been found to best answer the requirements, although, when recently made and bearing water of condensation, it does not appear to give such good differential staining as when dry or older. The white and yelk of an egg, with one-third its bulk of bouillon containing 1 per cent. of glucose, may on occasion be used, as also glycerine agar, which is, however, slower than serum, though yielding much better microscopic preparations. Dr. Park and Dr. Beebe claim that glycerine agar is not so reliable for diagnostic purposes as serum, and I have noticed that the growth of Löffler's bacillus on this medium is less luxuriant, while the cocci appear to develop more rapidly and vigorously. In making a culture the infected swab should be lightly but firmly passed over the surface of the slanted serum, but not with such force as to abrade it. The infected tubes are then kept in an incubator at 35° to 37° C. for, say, twelve hours, when the growth will be easily recognised. As a matter of fact, the cultures are set one day and examined next morning. Cultural characteristics are of value as affording collateral evidence of the presence of the specific organism, and on transparent media the colonies are more or less easily recognised. It is, however, on morphological characters and peculiarities of staining that reliance must be placed.

Staining.—A smear from a swab is made directly on a slide and is dried, fixed, and stained with Löffler's blue. In making a preparation from a culture a small drop of water is put on a slide by means of a platinum loop, and a portion representing the entire growth on the surface of the serum is removed by a platinum needle and evenly distributed in the water, and is then dried, fixed, and stained. A drop of cedar oil is put on the slide, and the examination made by a one-twelfth oil immersion lens. Staining directly on the slide, as in the recognition of bacillus tuberculosis, is quicker and handier than using a cover glass, and, with proper skill in using the objective, is practically safe.

Characteristics of the diphtheria bacillus.—It will be unnecessary to repeat the well-known descriptions of this organism, and I would only emphasise its great liability to variation in form and size. This tendency to "sport" is sure to puzzle the inexperienced observer, though, when understood, it becomes diagnostic. The organisms found in the exudate are often presented as diplobacilli, which stain more or less uniformly and at most show polar darkening, while in other and much rarer cases they are exceedingly characteristic, resembling those grown on serum and possessing strongly marked interruptions. The cause of this variation may possibly be found in the condition as to reaction, or composition of the mucous membrane or secretion, in the throats of different patients. This seems likely, as under artificial cultivation the character of the medium greatly influences the appearance of the bacillus. I may say that I have found these characteristic specimens most frequently in the exudates from adults. The variations shown in the bacilli of cultures are not, however, to be wholly accounted for by the character of the medium or by the temperature or staining manipulations. Cultures of different exudates grown together under conditions precisely similar, and stained in like manner, often show very different results. In some the bacilli may be uniform in shape, size, arrangement, and diagrammatic staining, while other specimens exhibit wide differences in all respects, presenting extremely long rods with wide interruptions, or clavate, fusiform, or even pyriform organisms of the most bizarre description. It is thought that these are involution forms, or, according to Dr. Klein, that they represent a relationship to a mycelial fungus. The variations are very interesting and invite further study.

Relation between the length of the bacillus and its virulence.—The results of Dr. Park and Dr. Beebe are not in accord with those of some others who hold that the longest bacilli are the most virulent. The observations of the above-named writers show that the greatest mortality occurred in those instances in which the rods were shorter than the average, while there was a diminished death-rate with the long forms and a still lower rate with the evenly stained short forms with badly marked characters. Ample opportunity was afforded by the records of the isolation hospital for learning the clinical history of the cases there, and from a comparison of such data with those obtained from the bacteriological examination the conclusion to be formed is in accord with that arrived at in New York—viz., that the bacilli afford little evidence on which to base a prognosis, but if anything the longer rods produce less fatal results than those of average dimensions.
